15. Root biennial. Stems proſtrate, ſmooth, finally terminating in flowers. Lower leaves many, almoſt as long as the ſtems, reſembling thoſe of After Tripolium, but thicker and more ſucculent. Among theſe ſpring three or four ſtems, ſometimes more round and having two or three joints, at each of which are two ſmaller leaves at the lower, and three or four at the upper joints. Surface in all ſmooth and even, and very minute white teeth about the edge, more perceptible in the ſmaller leaves, and the lower part of the others. Flowers uſually ſolitary, ſilvery white, opening in the middle of the day, and of ſhort duration. Peduncles ſhort, round or ſubquinquangular. Calyx large, acutely and deeply pentagonal, five-cleft; ſegments ſhortiſh, unequal, the two outer leafy, plane and large; the three inner leſs, with awl-ſhaped points, beneath which is a projecting ridge-like membrane. Petals extremely narrow, ſo as to be almoſt capillary, and not quite ſo long as the calyx; the inner ones ſhorter and more ſlender than the outer. Capſule very large, deeply five-angled, five-celled, very fleſhy, fleſh extremely hard and firm; cells very ſmall, filled with a few large ſeeds, which are kidney-form, wrinkled, and of a ſhining dark brown colour[8].

Native of the Cape. Cultivated in the botanic garden at Chelſea in 1700. It flowers from june to ſeptember[9].

16. Leaves numerous, either upright or bending upwards, rigid, thick and fleſhy, about a finger's length, appearing to be round, but ſlightly flatted on the inſide, eſpecially near the baſe; they are deep green and glaucous, thickly ſet with ſmall green dots and ſome tranſverſe lines, pointed at the end, the point purple or green. Flowers ſolitary, on a ſhort ſcape from the centre of the plant, large. Calycine ſegments unequal. Petals very narrow, white, ſhining like ſilver in the ſun, void of ſcent, opening about noon in july, auguſt and ſeptember. Style eight-cleft. Capſule eight-celled[10].

[1] Dillenius. [2] Hort. kew. [3] Dillenius. [4] Hort. kew. [5] Haworth. [6] Hort. kew. [7] Linn. ſuppl. [8] Dillenius, Haworth. [9] Hort. kew. [10] Dillenius.

Native of the Cape. Cultivated in 1717, as appears from Bradley[1].

17. Found at the Cape by Maſſon. Introduced in 1775[2].

18. This alſo was found at the Cape by Maſſon, and was introduced in 1774[3].

19. Root biennial. Stem ſhort, nearly the thickneſs of the little finger. Branches oppoſite, ſpreading very much, obſcurely angular or round, herbaceous, green, the lower ones procumbent and a foot and half long. Leaves thick, narrowing into a ſhort petiole or ſubſeſſile, entire, flat, ſomewhat waved, oppoſite on the branches, at the flowers ſingle, that is the flowers come out ſingly on a peduncle oppoſite to a leaf. Theſe, the ſtems, peduncles, calyxes and germs are covered with very minute ſhining dots, which when examined with a magnifier appear to be clear drops like ice. Calyx green and deeply five-cornered, three or two only of the leaflets run out into a ſpatulate blunt flat bractæ the length of the corolla: the others are ſmall and ſharp. Petals numerous, linear, ſharp, pale beneath, within fleſh-coloured, on the outſide red. The flowers have no ſcent, and are open from three to ſix in the afternoon[4].

Native of the Cape. Introduced in 1774 by Mr. Francis Maſſon. It flowers from april to october[5].

20. Root perennial. Stem rather ſhrubby, fleſhy, upright, much branched, roundiſh, ſmooth, covered, as well as the leaves and calyx, with depreſſed dots. Branches oppoſite or alternate, axillary, ſpreading, round, often very ſlender at their baſe, leafy. Leaves ſpreading, ovate-cordate, acute, entire, bright green on both ſides, and marked with a central nerve. Footſtalks half the length of the leaves, channelled, fleſhy. Stipules none. Flowers ſolitary, peduncled, erect, at firſt terminating, but afterwards becoming axillary from the protruſion of new branches. Calyx turbinated, fleſhy, four-cleft; ſegments acute, two oppoſite larger and broader. Petals ſcarcely ſo long as the calyx, very numerous, reddiſh purple, white at the baſe, and united; placed in three or four ranks, the inner ones gradually ſmaller. Stamens very numerous, ſhort, attached to the corolla. Germ half-inferior, ovate, marked with four or five furrows. Styles four or five, ſhort, recurved. Stigmas acute. Cells and valves of the fruit agree in number with the ſtyles[6].

Native of the Cape, where it was found by Maſſon, and others. Introduced in 1774. It flowers from may to ſeptember[7].

21. Root annual. Stems round, branching, purple, half a foot long or more, procumbent, the whole covered with icy blebs like M. cryſtallinum. Leaves lanceolate-wedge-form, bluntiſh, quite entire, flat, ſeſſile but drawn out into a long narrow tail at the baſe, the longeſt four inches in length. Peduncles axillary, ſolitary, round, one-flowered, three or four inches long. Flowers elegant, an inch and half in diameter, void of ſcent. Calyx five-cleft, with very unequal, fleſhy, ſpreading ſegments, two of them, almoſt oppoſite, include the corolla before it expands, when expanded they are only half its length, and end in a cowled ſharp tip: the three others are bluntiſh, ſomewhat ſpatulate, and about the ſame length with the corolla. Petals about forty, linear, ſharpiſh, flat, pale purple on both ſides with a deep red line along the middle. Filaments very deep red, ſhort, converging into a cone. Capſule depreſſed, five-celled[8].

Native of the Cape, where it was found by Maſſon. Introduced 1774. It flowers in july[9]. Jacquin ſays in may.

22. Leaves cluſtered, decuſſated, from an inch to two inches in length, deeply glaucous, flat above, but below produced into a ſharpiſh back, towards the end, both above and below, or on all the ſides armed with ſtiffiſh ſharp toothlets; they are ſmooth, and do not appear to be dotted unleſs they are held up to the light, but they have a few tranſverſe wrinkles. Peduncles from an inch to an inch and half and two inches in height, tender, round, uſually leafleſs, but ſometimes

[1] Hort. kew. [2] Idem. [3] Jacquin. [4] Hort. kew. [5] Smith. [6] Hort. kew. [7] Jacquin. [8] Hort. kew.

having

having a pair of leaves. Flowers solitary, terminating, the form and size of a Daisy, whitish with a tinge of purple, and streaked with a purple line along the middle of each petal both within and without; they spread out regularly in two or three rows, and are sometimes entire, sometimes cut a little at the end. They open about noon. Calyx divided into five equal glaucous segments. Capsule depressed, five-celled, terminated by five prominent starry points [a].

Native of the Cape. Cultivated in 1717, as appears from Bradley. It flowers from june to august [b].

23. Peduncles one-flowered, two-leaved. Corollas pale purple, sweet-smelling, not longer than the calyx. Stamens white, upright and forming a cone. Anthers yellow [c].

α. This grows to two feet and more in length, with a round stem, the thickness of a finger, twisted at bottom: from this at about two inches distance arise opposite branches, the bark of which on the lower part is brownish, on the upper yellowish, on younger plants and branchlets purple. They are almost covered with short thick leaves, the angles of which are almost equal; they have usually three, but sometimes only two tubercled teeth at the edge, ending in a purplish spinule; they are green with a glaucous bloom on them. From each pair of leaves bundles of three or four pairs spring out, which gradually become new branches. Flowers in a sort of umbel at the ends of the branches, smelling like May or White-thorn, pale purple, with only one row of petals, which are commonly entire and blunt, but sometimes slightly cut at the end. In warm weather the flowers continue open day and night.

β. This has larger and paler leaves, with toothlets of the same colour with the leaves themselves. Flowers somewhat larger and paler, rather more inclining to violet, and appearing three or four weeks later.

γ. Leaves somewhat longer, with an even or untoothed back, and the sides not so flat, but the inner part more bent in and somewhat more hollowed: the toothlets also, two of which there are on each side, stand out less, and are less spiny; they generally terminate in a purplish spinule. Flowers of a deeper colour more inclining to violet, more scattered: some of the petals more slender like threads. The stamens, when they have shed their pollen, diverge. The bark on the stem is more rough and fuller of chinks. It has the same smell with the others, like the flowers of Hawthorn: and it flowers in may and june [d].

Mr. Haworth remarks, that the plant is taller, more upright, more spreading, and every way larger than the other varieties. The leaves larger, whiter, longer in proportion, perfectly entire on the back or keel angle, and scarcely to be called even slightly denticulate on the edges. Flowers larger, of a pale rosy-purple colour, numerous, open in a morning as soon as the sun shines strongly upon them.

These varieties all agree in having triquetrous leaves, shaped like the Greek *delta*, of a smooth and even surface, appearing porous when held up to the light. The capsules are turbinate and five-celled [e].

Native of the Cape. Cultivated in 1714, by the Dutchess of Beaufort [f].

24. The leaflets of the calyx being bearded at the tip, as well as the leaves of the plant, shows the origin of the perianth. The least interior petals, which surround the stamens, are white [g].

α. Stems somewhat woody, slender. Branches procumbent, frequent, soft and brittle when green, but becoming tough and flexible when dry, round, somewhat cinereous, having a pair of leaves at short intervals at each joint, ending bluntly, tubercled, netted like a serpent's skin, appearing dotted when held to the light, having five, six, or seven radiating spinules at the end, at first greenish, then brownish, and at length black, with a black dot in the middle of them: the leaves are not properly round or cylindric, but have the upper part somewhat flat, and the lower convex: their colour is deep green and glaucous. Flowers few, commonly solitary, middle-sized: petals in a single row, commonly entire, but sometimes slightly cut at the end, of a fine purple inclining to a vivid violet and shining: they are nearly of the same size, except a few in the middle, which are much narrower and paler. The flowers open, when the sun shines from seven or eight in the morning till noon, but shut soon after noon although the sun shine. They open several days successively, and have a scarcely perceptible Hawthorn smell [h].

Mr. Haworth remarks, that the leaves are very remote, in comparison with the other varieties, nearly cylindrical, with a just perceptible attenuation towards the points, and very slightly plane above near the base; they are also smaller than the next variety, and beautifully studded with largish regular tubercles or polished papulæ, which are roundish-ovate, smooth, and when closely examined, bear no small resemblance to fine shagreen. Peduncles an inch or more in length, entirely destitute of hairs, thickening near the calyx, covered with minute shining papulæ. Calyx smooth and papulose; two of the segments much longer and stouter than the rest, leafy, the third segment larger than the remaining two, but much less than the former; the two remaining segments are much shorter and less, with membranaceous edges, but rarely any radiating hairs or spinules. Petals fine bright purple within, paler without, not very numerous; inner ones paler and extremely narrow. Filaments white, stout, shortish, some, though rarely, with white papulose ascending hairs at the base. Anthers largish, yellow, oblong, furrowed. Styles five, greenish, broad at the base, but sharply awl-shaped and short. Capsule five-angled, small, five-celled, not fleshy.

β. The plant is sessile or stemless the first and second year, but afterwards acquires a low stem and reclining branches, dividing into many short branchlets, on which the leaves grow very close: these are swelling on the inner or upper part rising a little, on the lower or outer rounded; they are subhirsute, being very closely set with short hairs disposed in form of a lengthened net, and have whitish spinules at the tip radiating from a yellowish centre; their colour is cinereous glaucous. The flowers come out later, namely in september and october; they are somewhat smaller and pale, purple tending to pale violet and shining; petals narrow, entire, almost all of the same size. Styles eight, very short, greenish yellow. Capsules eight-celled. Calyxes five-cleft, three segments longer, thicker, round, resembling the leaves, two shorter, more slender, concave: the former hairy at the tip, the latter below. Sometimes the calyx is six-cleft. Peduncles an inch long, yellowish green, hairy especially towards the capsules, which abound so in longer hairs as to be lanuginose [i].

Linnæus suspects it to be a mule, and says that it differs in having the calyx six-leaved, with six styles and cells; the peduncles hispid, and the leaves imbricate.

Mr. Haworth is at a loss to conceive how Linnæus could unite this plant with his barbatum; since they agree in nothing but their radiating points and purple flowers; and even in the first circumstance they differ as to number, α having three or five radiating hairs, and β often above a score, at the end of the leaves: α has also cylindric leaves, smooth papulæ, short hirsute branches, smooth peduncles, a five-leaved smooth calyx, five styles, and a five-celled capsule; β has semicylindric leaves, rough bristle-pointed papulæ, trailing elongated smooth branches, hairy peduncles, calyx six or seven-leaved, hirsute, six styles, and a six-celled capsule [k]. There must be a mistake in one circumstance, for β has short hirsute branches, and a smooth elongated one.

γ. This resembles the preceding so much, that the difference is scarcely apparent, unless they are observed very carefully. It might be taken for a younger plant of the other; however the cuttings never protrude such thick and long leaves: the spinules of this are longer, thicker, more rigid, and more hoary, and old

[a] Dillenius. [b] Hort. kew. [c] Linn. [d] Dillenius. [e] Idem. [f] Hort. kew. [g] Linn. [h] Dillenius. [i] Idem. [k] Haworth.

plants grow leſs to ſtalk, and throw out fewer and ſhorter branches. The colour of the leaves is the ſame, unleſs perhaps they may be in this ſomewhat more intenſely glaucous [4].

Mr. Haworth, who erects theſe and other varieties into ſpecies, conceives this to differ from α, in having ſemicylindrical, denſely imbricated, larger leaves, with hiſpid peduncles and calyxes; and from β, in being nearly ſtemleſs, having larger leaves, denſely imbricated, and almoſt ſmoothly papuloſe, covering every part of the ſtem, and ſix-leaved calyxes nearly equal.

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from june to auguſt [5].

25. Peduncle very rugged downwards rather to the ſight than the touch. Calyx awnleſs. Flower ſweet-ſmelling, very like that of the preceding, from which perhaps it originally ſprung, loſing the beard of the leaves, and having it ſcattered over the ſtem.

α. Stems and branches from a foot to a foot and half and two feet in length, numerous, ſpreading every way, ſlender, the lower joints ſwelling out into knots, an inch or ſomewhat more diſtant. Leaves dark green and generally glaucous, but ſhining with innumerable icy globules cloſely heaped together, and putting out from the axils, one, two, or three ſmaller pairs; they are ſtraight, thickiſh, and being very blunt at the end they frequently hang down by their weight. Stem and branches ſmooth at bottom; but towards the middle and on the upper branches very hairy. Flowers terminating and axillary on longiſh peduncles, rather large, compoſed of looſe entire petals in a ſingle row, of a deep bright purple colour. Capſules ſmall, five-cornered, exhibiting when ripe a pentagon ſtar. Older plants have ſhorter leaves and peduncles. The icy globules are leſs protuberant in this than in γ, and more confluent, ſo that the leaves appear wrinkled with them [1].

It is a low divaricating ſhrub, covered with white ſcattered ſhort hairs, pointing different ways. Confined in a pot, it never takes root at the joints; but in the full ground the branches trail and ſometimes ſtrike root. Leaves of equal thickneſs to the very points, and ſometimes flattiſh above, covered with roughiſh cryſtalline papulæ, and looking like ſhagreen. Flowers opening in a morning, pretty numerous, making a fine appearance. Peduncles ſlender, thickened above, covered with divaricating white hairs, which gradually diſappear near the calyx, by becoming extremely ſhort pileſcent papulæ. Calyx ſmooth, covered with ſpangling papulæ; ſegments nearly equal, blunt, concavo-convex. Petals ſcwer than in ſome ſpecies, linear-lanceolate, entire or with one or two indentures at the points. Filaments purple, of different lengths. Anthers and pollen buff-coloured. Styles ſmall, greeniſh. Capſule deeply five-angled, five-celled [2].

β. This is lower, more branched and leſs upright than the preceding. Leaves paler, with ſmaller icy globules, ſomewhat longer and narrower, not ſtraight but curved inwards, leſs thick at the ends. Stems and peduncles leſs hiſpid. Flowers pale purple, ſomewhat ſmaller, with the petals nearer together; ſtamens ſhorter, not all incumbent on the petals, but many collected into the form of a bottle in the centre. The flowers are numerous, axillary, on one ſide only or on both ſides, on ſhorter and leſs leafy peduncles. By age this plant becomes much branched and twiſted, not exceeding a foot in height.

γ. Flower the ſame ſize as in α, but of a paler colour. Leaves ſhorter and narrower. Stems with ſhorter hairs on them, like β, which it reſembles in the narrowneſs of the leaves, but they are ſhorter and have larger icy globules; the flowers alſo are larger and of a deeper purple. It differs from both in having the calyx and baſe of the fruit very hairy, in having the petals marked along the middle with a ſtreak of a deeper purple, and the ſtamens collected into a ball, and never ſcattered; they are of a pale green with a red circle in the umbilicus [3].

[4] Dillenius. [5] Hort. kew. [1] Dillenius. [2] Haworth. [3] Dillenius.

Mr. Haworth regards this as ſpecifically diſtinct from Linneus's hiſpidum, from which, he ſays, it is very readily to be diſtinguiſhed by the peduncles and calyxes being very denſely covered with woolyiſh hairs, and by the face of the plant itſelf. The uppermoſt parts of the peduncles of α, and every part of the calyx are not only deſtitute of hairs, but adorned with large ſpangling cryſtalline papulæ. The leaves are covered with much rougher papulæ. The ſtems and branches are uſually covered with much longer and much thicker ſet hairs. This is a more robuſt plant, with ſtouter branches, and bolder flowers, with broader denſer petals.

M. ſtriatum opens its gay ſtriated flowers in the forenoon, is very often in bloom, and the flowers being numerous, they make a fine appearance when expanded, but are handſomeſt the firſt time of opening, for they loſe their gayeſt colours long before they fade quite away [1].

Native of the Cape. Cultivated in 1705, by Charles Du Bois, Eſq. It flowers the greater part of the year [2].

26. Leaves ſhear, ſemicylindric, channelled-flat, opaque, with villoſe hairs ſcattered over them, eſpecially at the baſe. Stem pubeſcent, with villoſe hairs ſcarcely ſtanding out [3].

Plant hairy, proſtrate, finally ſhrubby. Branches in diſtant pairs, croſſing each other, axillary, cylindrical, covered with the permanent, cylindrical, hairy ſheaths of the connate leaves; whoſe hairs are not very thick ſet, but ſhort, white, and rather preſſed to the ſtem; ſome of them expanding, but pointed upwards. Leaves leſs ſucculent than thoſe of any other ſpecies, connate but appearing diſtinct, unleſs attentively examined; they are linear, ſcarcely pimpled, or if ſo, the pimples are extremely minute, ſhining in the ſun, and of a dark green colour; they are channelled above, with a convex or rounded keel, ſlightly attenuated both ways, rather dilating again at the very baſe, and embracing the ſtem, where they are quite deſtitute of ſucculency, and ſlightly membranaceous at the edges, with a white midrib: the membrane at the baſe is ciliate; the reſt of the leaf nearly ſmooth, or having diſtant ſmall white hairs ſcattered over both ſides. Flowers ſolitary, terminating, rarely ſeen, opening to a very warm ſun only, in the forenoon [4].

Native of the Cape. Cultivated in 1759, by Mr. Miller [5].

27. Height from a foot and half to two feet. Stem not very ſhrubby, nor very thick. Branches woody, the thickneſs of a ſtraw, procumbent, round, covered with an aſh-coloured bark; the upper ſhoots of a yellowiſh bay colour, becoming pale herbaceous; they are broadiſh immediately under the flowers, thence gradually more ſlender, ſlightly compreſſed, and winged on each ſide with a proceſs from the back of the leaves. Leaves difform; thoſe which are faſtened to the peduncles (bractes) ſhort and thick, the others longer and not ſo thick, with other ſmaller leaves from the axils; all uncinate, ſubglaucous, rugged with frequent tubercles of the ſame colour, which held up to the light appear to be ſo many porous dots. Flowers on peduncles from an inch to two inches in length, alternately axillary, ſmall, pale purple, petals twiſted about, narrower towards the baſe, broader towards the end, entire, in a ſingle row, ſmelling like thoſe of Hawthorn, open both day and night, for a long time and in great abundance, there being a ſucceſſion of them from july to october [1].

Mr. Haworth thus deſcribes the two bractes. They inveſt the peduncles juſt beneath the calyx, which they partly embrace; they are broad, ovate, ſharply keeled, dotted, membranaceous towards the edges, and terminating in a ſmall recurved point, ſimilar to the little cartilaginous hooks which terminate the leaves on the branches. Calyx five-cornered upwards, taking its angles from the keels of the ſegments, which are dotted, nearly equal, or two plane and ſomewhat leſs than the other three, which are rather longer and membranaceous

[1] Haworth. [2] Hort. kew. [3] Linn. [4] Haworth. [5] Hort. kew. [1] Dillenius.

towards the edges; all the ſegments are much broader at the baſe, or ſubulate keeled, or triquetrous, reſembling the leaves, and ending in ſimilar recurved cartilaginous points. Petals numerous, the outer ones very long and narrow, unequal, bright purple; the next row much ſhorter and narrower, unequal, purple above, whitiſh-yellow at the baſe; the third or innermoſt very ſhort, unequal, ſtill narrower, converging, all yellow, reſembling filaments in ſtructure, ſhining in the microſcope with beautiful ſpangling cryſtalline mamme papillæ, tapering to a very ſlender hair-like point, and quite covering the real filaments from the ſight. Theſe are very few, ſhort, and ſlender or almoſt capillary, with very ſmall, whitiſh buff anthers. Germ ſmall, ſmooth. Styles very ſhort, green. Capſule five-angled [a].

Native of the Cape. Cultivated in 1732, at Eltham, by James Sherard, M. D. [b]

28. Stems woody, at bottom bay, the branches yellowiſh brown, procumbent, round at bottom, but ſomewhat angular above, the peduncles however are round. Leaves acutely triquetrous, glaucous, ſomewhat ſhorter and thicker, rougher and more rigid, with frequent tubercles larger and whiter, eſpecially on the back, than in emarginatum. Flowers ſolitary, few (two or three), violet purple and ſhining, but becoming paler, opening two or three times, before and after noon. Petals moſtly of the ſame ſize, entire or ſlightly cloven at the end, firmly connected at the baſe, they end ſuddenly in filaments, which are not ſcattered, but collected into a head about the ſtamens, like a crown. Capſules thicker, rounder, and leſs angular than in emarginatum [c].

Mr. Haworth deſcribes it as a ſhrubby upright plant, with the branches crowded, oppoſite and alternate, covered with a dark-coloured bark. Leaves more crowded, much greener, and covered, eſpecially on the keel-angles, with rougher, more projecting and more cryſtalline papillæ than thoſe of emarginatum. Peduncles ſmooth below, roughening upwards towards the calyx, with two leafy bractes about the middle. Calycine ſegments equal, three of them edged with dark-coloured membranes. Petals paliſh purple, numerous, linear, with from one to five irregular minute teeth. Filaments buff-coloured and ſhort, with large buff-coloured anthers, and pale pollen. Germ ſix or ſeven-angled, ſmooth. Styles ſix or ſeven. Capſule ſix or ſeven-celled.

Native of the Cape. Cultivated in the Eltham garden in 1732 [d].

29. Leaves between papuloſe and tubercled; much rougher, more glaucous, and more acutely pointed, than in any other reptant ſpecies. The branches are angular, and finally ſomewhat woody. In its triquetrous leaves and reptant ſtems it is allied to auſtrale and craſſifolium. In the open air, it will extend the branches above a foot and half every way, and they will be fixed firmly to the ground at every joint by ſtrong fibres [e].

Native of the Cape, where it was found by Maſſon. Introduced in 1774. It flowers in july and auguſt [f].

30. Shrubby but procumbent; even when tied up, its irregular twiſted branches will hang down; they are round towards the top and of a yellowiſh bay colour, but quadrangular at bottom. Leaves ſmaller, mucronate, curved inwards, in bundles, acutely triangular, deep green and glaucous, having ſmall dots and tubercles. Flowers ſeveral, terminating, middle-ſized, with ſcarcely any odour, on ſlender oblong peduncles. Calycine ſegments ſometimes hooked, ſometimes not. Petals very many, lying one over the other; the outer larger, bifid or trifid at the end; the inner ones gradually ſmaller, entire, but not filamentoſe: they are of a moſt vivid violet purple colour, but the flowers expand only about noon, when the ſun is very hot. Stamens not numerous, ſhort, neither very much ſcattered, nor collected, but ſpreading. The flowers continue long, and open ſeveral times if the ſun ſhines hot [g].

[a] Haworth. [b] Hort. kew. [c] Dillenius. [d] Hort. kew. [e] Haworth. [f] Hort. kew. [g] Dillenius.

It differs from ſcabrum, which it otherwiſe reſembles, in the frequency and twiſting of the branches, in having narrower leaves, leſs rough, of a deeper green, the flowers ſmaller, compoſed of more numerous petals of a deeper ſhining colour; but the chief difference is in the ſtamens, which in that are collected in a head, which is not the caſe in this [a].

Native of the Cape. Cultivated in the Eltham garden in 1732. It flowers from june to auguſt [b].

31. α. Stems ſlender, round; branches more frequent than in variety β, more reclining, with much ſmaller and more recurved leaves, having only one ſhort ſpinule at the back; they end in a ſpinule as that does, but it is ſhorter and whitiſh, whereas in β it is purpliſh. Stems and branches, though rigid, yet are procumbent. The leaves, and internodes, which are elongations of the leaves inveſting the ſtems, are dotted with ſmaller dots than in β; they are both of a fuller glaucous green colour, and not ſo white; the bark alſo of the ſtem is not ſo white, but rather of a yellow and brown duſky whitiſh colour. The internodes are thickened above, and narrower beneath. Flowers axillary on leafy peduncles, ſmaller than thoſe of β. Calycine ſegments equal, glaucous.

β. Stems ſlender, not much bigger than a ſtraw, ſomewhat woody, rigid, round at bottom, covered with a thin white cuticle, higher up compreſſed, below upright and not much branched, but where there are more branches and leaves, they hang down. A palm or a foot from the bottom the ſtem and branches become glaucous and have herbaceous internodes, compreſſed and thicker above, covered with a thick fleſhy bark. Leaves perforated, three-ſided, with unequal angles, the back being more produced and ſharp, the upper part narrower and ſlightly elevated, the lateral angles blunter than the lower. There are prickles at the end and on the back of the leaf: in young plants only one on the back, in older ones two or three, of a duſky purple colour. Leaves and internodes permanently glaucous, and dotted with green dots. Calycine ſegments two larger, ſpiny; three ſmaller, not ſo. Petals pale purple, narrow, the inner ones gradually ſmaller and filamentoſe. Capſules terminated by five ſharp purple tubercles. The flowers expand only in hot ſeaſons [c].

Mr. Haworth is convinced that this is diſtinct from α; the leaves and branches being not only larger and almoſt white, but the former having uſually three ſometimes four teeth or ſpines under their points, when full grown: whereas the leaves and branches of α are not much above half the ſize, nearly of a green colour, with never more than two teeth or ſpines below the points. Flowers purple, of a good ſize, but not ſhowy, axillary and ſeſſile from the uppermoſt leaves, and opening in a morning.

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from june to auguſt [d].

32. This is an upright thorny ſhrub, from two to three feet high, much branched. Branches oppoſite, axillary, aſcending, roundiſh-compreſſed, with a ſmooth cinereous bark, throwing out in various places branching ſpines. Leaves in pairs, at an interval of an inch or an inch and half, glaucous, with frequent green dots, pellucid when held up to the light; all the angles blunt, ſlightly ſwelled at the inner baſes, very firm to the touch, terminating in a very ſmall white cartilaginous point or harmleſs brittle. The upper leaves are much ſhorter. Spines appear as if terminating, but ſoon ceaſe to be ſo, from the protruſion of young ſhoots; they are branched, nearly horizontal, divaricating and trichotomous, each from half an inch to an inch in length, awl-ſhaped, very ſharp, reſembling thoſe of our common Hawthorn, but not ſo ſtrong or pungent, covered with a grayiſh bark, and beſet with a pair of diſtinct, oppoſite, chiefly barren leaves, like thoſe of the branches, but only a third of the ſize. Flowers ſmall, pale violet purple, on ſlender, leafleſs, green peduncles: petals blunt, equal in ſize. Calycine ſegments equal [e].

[a] Haworth. [b] Hort. kew. [c] Dillenius. [d] Hort. kew. [e] Haworth. Dillenius.

Native of the Cape. Cultivated in 1714 by the Dutchefs of Beaufort[a]. The long winter of 1729 deſtroyed it in the Eltham garden. It flowers late, at the end of auguſt and in ſeptember[b]; or, according to the Kew catalogue, from june to auguſt.

33. This forms a low, much branched, ſpreading ſhrub; and when old, has a very large tuberous root, ſometimes as big as a man's head, partly protruded above the ſurface[c]. Stem woody, very thick at bottom, covered with a bay-coloured bark. Branches bending and twined. Leaves ſtuart, bluntly triquetrous, with the back convex, the inner or upper ſurface ſomewhat ſwelling, ſubglaucous, with ſilver dots, ſo ſmall as not to be viſible except when the ſun ſhines. Flowers at the ends of the branches, on ſlender, cinereous or reddiſh peduncles; they are ſmall, of a pale red or vinous colour; petals not numerous, broadiſh, blunt, equal in ſize. Stamens collected into a bottle in the middle. Calycine ſegments ſhort, equal. Capſules roundiſh, remarkably ſmall when ripe. It flowers about noon[d].

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from june to ſeptember[e].

In old plants the extreme branches ſometimes become thorny; theſe thorns are the peduncles of the preceding year. Thorns alſo come out from the forkings of the branches ſometimes inſtead of flowers[f].

34. Stems woody, procumbent, ſlender, round, with a yelloviſh bark. Branches from each of the upper axils. Leaves on the inner ſurface flat, on the outer convex, bright green inclining to gray, from their ſlenderneſs often hanging down, appearing dotted when held up to the light. Flowers at the ends of the branches, ſolitary, on long ſlender peduncles; they are large, eſpecially on young plants, pale ſcarlet, ſhining and appearing powdered with gold duſt in full ſunſhine: petals very numerous, the inner ones gradually ſmaller, entire or cuſpidate at the end, ſometimes ſlightly bifid, cohering at bottom. Flowers abundant, and opening ſeveral days ſucceſſively about noon, eſpecially in june. Stamens very numerous, ſanguinole at the baſe. Style villoſe. Capſule large, fleſhy, from round bluntly five-angled[g].

Mr. Haworth remarks, that in many ſtages of its growth this is very liable to be taken for bicolorum and his ſpiniforme; and that this frequently emits roots from the joints of its ſtems, and thereby becomes creeping.

Native of the Cape. Cultivated in the botanic garden at Chelſea in 1700. It flowers from june to ſeptember[h].

35. Plant upright, woody, firm, growing to a larger ſize than moſt of the ſpecies. The flowering ſtem is rigid and ſomewhat gray. Branches axillary, oppoſite, from erect ſpreading, croſſing each other in pairs, and beſet thickly with young leaves on their firſt outſet, whiniſh or glaucous but finally browniſh, gradually ſhorter upwards, forming a beautiful pyramidal glaucous plant, well covered with fine leaves. Theſe, when full grown, are from two to three inches long, ſlightly curved upwards or falcate, very glaucous, croſſing each other in pairs, very much compreſſed at the ſides, having pellucid dots ſcattered over them, ſtuartiſh above, mucronate. Flowers terminating in a ſort of corymb, large, ſhowy, purple[i].

Native of the Cape. Cultivated in the Eltham garden in 1723.

36. Native of the Cape, where it was found by Maſſon. Introduced in 1774. It flowers from july to ſeptember[k].

37. This is a ſmall very low ſpreading or trailing ſhrub. Branches crowded, oppoſite or alternate, axillary, at firſt aſcending, but finally deflected. Leaves oppoſite, diſtinct, awl-ſhaped, of different lengths, dotted, ſcarcely to be called ſmooth, but not ſo rough as thoſe of emarginatum. Flowers paler, on long, compreſſed, ſmooth peduncles. Calycine ſegments nearly equal, three with membranaceous edges. Petals numerous, pale purple, very narrow. Germ ſmooth, green, ſhining, truncate at top with a hollow or navel. Filaments numerous, converging into a conical or cylindrical figure in the centre, buff-coloured and ſlender. Styles ſtout, awl-ſhaped, long, ſpreading, rough above. Capſule five-angled, five-celled. Flowers from july to october[l].

Native of the Cape, where it was found by Maſſon. Introduced in 1774[m].

38. Native of New Zealand, where it was found by Sir Joſeph Banks. Introduced in 1773. It flowers in july and auguſt[n].

39. Stems a palm or long ſpan in length, creeping, when young herbaceous and ſoft, three-ſided, green, frequently purple next the ſun; when old, more round, ſtill not woody but ſoft, tough and fungoſe, covered with a cinereous bark. Leaves uſually in the ſame plane, or not deciuſtate, divaricating, or not approximating like many of the other ſpecies, thick, ſucculent, bluntly three-ſided, ſmooth and ſomewhat ſhining, green. Flowers on ſhort peduncles, ſometimes naked, but more frequently with a pair of leaves on them; they are ſolitary, ſmall, violet purple; petals not very numerous. Stamens many ſhort, not very much ſcattered, but not collected into a head or upright. Anthers pale yellow. Calycine ſegments two longer. Capſules ſmall, terminated by blunt angles at top. This plant creeps ſo much that it ſeldom flowers, and when it does the flowers do not continue long[o].

Mr. Haworth remarks, that the leaves, which are far from ſucculent or thick, when compared with many others, are generally more triquetrous than ſemicylindrical; that it is a handſome plant, thickly furniſhed with leaves; and that the branches, which ſometimes hang full a yard from the pot, are naturally proſtrate and reptant, angular and ſlender.

Native of the Cape. Cultivated in 1727, by Richard Bradley, the firſt profeſſor of Botany at Cambridge[p].

40. This is a very low, buſhy, divaricating almoſt decumbent ſhrub, rarely more than ſix or eight inches high. Branches oppoſite, ſlightly angular, axillary, divaricating and denſely crowded. Leaves very minute and much crowded, glaucous, having ſmooth pellucid dots, attenuated at the baſe, very gibbous on the keel, ſharply incurved or falcate, near a quarter of an inch long, and ending in an acute white juſt perceptible briſtly point, in the direction of the leaves. Flowers purple, large, ſolitary, opening in the morning, on ſhort terminating peduncles. Calycine ſegments nearly equal, two leafy and three membranaceous at the edge, all acute. Petals linear, numerous, emarginate. Filaments numerous, ſlender, pale purple, converging. Styles yellowiſh-green, awl-ſhaped, long. The leaves ſometimes are ſo much incurved as to form half a circle, and they are remarkably ſmall[q].

Dillenius compares this with the next ſpecies, and remarks that it is much ſmaller in all its parts, with ſhort woody ſtems, which produce many ſhort bending branches, much interwoven in old plants. Leaves very ſhort, narrow, ſmooth, glaucous with a purple tip, appearing dotted when held up to the light: in young plants they are longer and not ſo much crowded. It flowers abundantly during great part of the ſummer, and the ſame flowers open ſeveral times. They are ſmaller than thoſe of the next ſpecies, of a deeper purple colour, and ſmell like bruiſed Peach kernels. Capſule much ſmaller, brown purple.

Native of the Cape. Cultivated in 1727, as appears from Bradley.

This ſpecies is omitted in Syſtema Vegetabilium, and the trivial name of *falcatum* is put to the ſpecific difference of M. acinaciforme[r].

41. This is a ſmall, very buſhy, rather glaucous ſhrub, from ſix inches to a foot or more in height. Branches almoſt upright or often diffuſe and panicled, round whilſt young, ſlightly angular when old, covered with a brown bark, for the moſt part oppoſite and crowded. Leaves alſo oppoſite and crowded, rather glaucous, having pellucid ſpots, uſually diſtinct but

[a] Hort. kew. [b] Dillenius. [c] Haworth. [d] Dillenius. [e] Hort. kew. [f] Dillenius. [g] Idem. [h] Hort. kew. [i] Linn. Haworth. [k] Hort. kew. [l] Haworth. [m] Hort. kew. [n] Idem. [o] Dillenius. [p] Hort. kew. [q] Haworth. [r] Hort. kew.

ſometimes

ſometimes confluent; they are ſubtrigonous with blunt angles, awl-ſhaped, attenuated at the baſe, ſlightly incurved, ſometimes almoſt ſabre-ſhaped, from three quarters of an inch to an inch and half in length. Flowers very numerous, reddiſh purple, like thoſe of M. deltoides, but more handſome, expanding in the fore part of the day in ſuch profuſion as often to cover the ſurface of the plant. Peduncles ſolitary, longiſh, thickening upwards, forming a kind of divaricating panicle. Calycine ſegments nearly equal; ſometimes two leſs, and membranaceous all round, with ſharp leafy points beneath the membranes. Petals linear, numerous.

It is a very variable little plant, but not in the leaſt liable to be taken for any other ſpecies; it aſſumes different appearances, according to its treatment, and the different ſtages of growth. The very numerous beautiful purple flowers, covering the whole plant, and produced every ſeaſon, make this a valuable ſpecies'.

Native of the Cape. Cultivated in 1732 by James Sherard, M. D. It flowers from june to auguſt'.

42. This is a ſlender branched woody ſhrub, two feet high or more. Branches divaricating, cylindric, when young greeniſh and covered with cryſtalline papulæ; when old ſmooth, wiry and ſlender, covered with a browniſh bark. Leaves in old plants very ſhort and numerous, diſtinct; whilſt young ſlightly incurved, when old ſpreading and pointing four ways; in all ſtates ſhining with very minute papulæ. Flowers ſolitary, bright reddiſh purple, reſembling thoſe of the preceding, terminating the little ſhort lateral branches, and opening in the forenoon. Peduncles ſhort, cylindric, covered with ſmall ſpangling papulæ. Filaments very numerous, purple, ſpreading and of different lengths. Anthers and pollen buff-coloured. Styles large, ſulphur-coloured. Capſule ſwelling above the entire part of the calyx, where it is deeply five-angled, each angle with a grooved line down the back, marking the points in which it is to open when ripe.

This ſpecies puts on very different appearances, according to its age and the treatment it receives. In the full ground, under a ſouth wall, in a poor ſoil, the leaves will be above an inch in length and nearly ſemicylindric, and the young ſhoots will be covered with pileſcent papulæ, pointing downwards, and appearing in a microſcope like minute hooks of glaſs or ice. Whereas the leaves in the ſtove, when not luxuriant, are ſeldom a quarter of an inch in length, and the papulæ are not pileſcent*.

Native of the Cape, where it was found by Maſſon. Introduced in 1774. It flowers in july and auguſt'.

43. The texture and form of the leaves is almoſt the ſame as in M. corniculatum, and they come out in bundles at intervals in the ſame manner; they are not however ſo bluntly triquetrous, that they have not the two very long leaves, and that they are rounder, ſmoother, more frequent, longer and more ſlender, tougher and more pliant.

It had not produced flowers in the Eltham garden, although it had been cultivated there many years before 1732'. They come out from the lower axils of the leaves on the branches, on ſhort peduncles; the calyx is equal and middle-ſized; the corolla purple with lanceolate-linear petals; the ſtamens are whitiſh*.

44. Plant trailing on the ground, diffuſe, and extending from half a yard to a yard in length, the lower part aſh-coloured and round, the upper purple, ſlightly compreſſed, and having, as it were, two angles, whence the leaves ſpring. Branches ſcarcely to be called ſix-angled, being chiefly ſemicylindric or triangular, often purpliſh and crowded. Leaves an inch and half long, appearing dotted when held up to the light, ſcarcely connate; the angles edged with a faint perceptible cartilaginous margin, which is rough to the touch, and finely ſerrulate when nearly viewed, and on the keel-angle largeſt and coarſeſt; the lower ones are longer and ſtraighter, the upper ones and thoſe that come out from the joints are ſhorter and incurved, the younger and middle leaves are ſickled inwardly, the outer and older ones are ſickled outwardly. Flowers terminating the ſmaller branches, ſolitary, not ſmall, purple, pretty but not ſhowy, on pedunckes two inches long, with a pair of leaves on each; the inner petals gradually ſmaller, and the innermoſt filamentoſe. Calycine ſegments unequal, two longer and three ſhorter, membranaceous'.

45. Branches three quarters of a yard or a yard in length, at firſt aſcending, but afterwards incapable of ſupporting themſelves in an erect poſture, they become deflexed or incumbent. Leaves ſhaped ſomewhat like a ſabre or cimeter, ſlightly bent in, the inner part next the branch flat or ſlightly hollowed in the middle, the outer compreſſed and produced into a ſharp back, the outer edge, eſpecially in the upper part, ſlightly crenated; they are glaucous-green, except at the end, where they are uſually purple, ſmooth but not ſhining, and not porous. Flowers large, three inches in diameter, handſome, of a very vivid ſhining purple colour, paler towards the middle, compoſed of numerous petals, almoſt equal, in three or four rows. Anthers oblong, whitiſh. Style multifid, dividing into twelve ſhort, thickiſh, cirrhoſe, greeniſh parts. Calycine leaflets thick, three-ſided, of which three are membranaceous. Capſule twelve-celled, large, fleſhy, turbinate, cornered and as it were winged with two lines on each ſide that ſtand out a little.

This ſpecies very ſeldom produces flowers, it flowered however in the Eltham garden in the year 1732, at the end of april*. It had been cultivated earlier, named in 1714, by the Dutcheſs of Beaufort'; but whether it flowered in the garden at Badminton we are not told. According to the Kew catalogue it flowers in auguſt and ſeptember.

46. This is a decumbent plant, whilſt young almoſt herbaceous, becoming ſhrubby by age. Branches weak, procumbent, ſhort, often pendulous, ancipital, moſtly in pairs from the axils of the leaves; which have ſhort harmleſs ſpines at the point, like herbaceous ſerratures; ſometimes a few very ſhort harmleſs ſpinules appear towards the points both on the lateral and keel angles, thoſe on the keel ſlightly recurved and weaker than the others. Flowers as large as thoſe of *bellidiflorum*, and much like them, but of a ſomewhat deeper ground colour, with a higher-coloured line of purple up the middle of the petals, and not ſo pale on the outſides, opening in the forenoon. Pedunckes angular, terminating, long, one to three from the ſame origin; when only one, inveſted with a pair of bracteal leaves juſt below the middle, like the leaves of the branches: lateral pedunckes much leſs and ſhorter than the central one, each ſupporting one flower, and often furniſhed with a pair of bractes. Calycine ſegments equal, three with ſlight membranaceous edges. Petals numerous, in one row, equal, broad-linear, with from one to three notches at the point. Filaments numerous, converging or arched over the ſtyles and germ, purple. Anthers ſmall, paler. Styles very ſhort, ſpreading, or rather five ſtigmas with roughened feathery purpliſh points. Capſule hemiſpheric, five-angled, five-celled; cells ſmall and dry. Seeds few in the green capſule, white, oval-kidney-ſhaped.

Native of the Cape. Flowering in ſeptember and october, but rarely producing flowers'.—Cultivated in 1758, by Mr. Miller*.

47. This is a ſhrubby plant, not erect. Branches oppoſite and alternate, axillary, rather crowded, generally aſcending, but ſometimes almoſt decumbent; whilſt young, ſtout, greeniſh or purpliſh green and angular; when old, long, brown, woody, ſtrong and cylindrical. Leaves of different lengths, according to their own ages and that of the plant, from two to five inches long, and not a quarter of an inch broad. The young leaves uſually aſcending, incurved, very glaucous, with pellucid, very numerous, well-defined punctures; the old ones expanding or recurved, glaucous and dotted; all oppoſite, connate, and ſwelled juſt below the baſe where they unite, and awl-ſhaped above, ſlightly compreſſed, with the angles very entire;

* Haworth. † Hort. kew. ‡ Haworth. § Hort. kew. ‖ Dillen. elth. ¶ Linn.

* Dillenius, Haworth. † Dillenius. ‡ Hort. kew. § Haworth. ‖ Hort. kew.

the keel-angle ſometimes ſlightly cartilaginous in the young leaves. Flowers ſolitary, very large and ſpecious, bright purple, making a fine contraſt with the very glaucous leaves and deep brown branches [f].

Mr. Curtis remarks, that the leaves ſometimes throw out internally a tooth near their extremities, and that it has been introduced within theſe few years, moſt probably from the Cape, by Mr. Maſſon.

48. Leaves the thickneſs of a finger, ſhining, long, with a cartilaginous rugged keel [g]. They are curved in or ſickled, but ſo as the curvature verges to the inner flat ſide, not the outer acute one; they are ſometimes of a darker, ſometimes of a paler green, frequently purple at the end. Flowers three inches in diameter, yellow, ſhining in the ſun. Calycine ſegments four, two longer, two ſhorter, ſometimes membranaceous at the edge, and hooked at the back, with frequently a fifth leaf, thicker and longer than the others, and more like the ſtem leaves. Petals very many, the inner ones ſmaller, entire, more or leſs cuſped. Stamens very numerous, ſaffron-coloured, with yellow anthers. The ſtyle divides into eight, ten or eleven curled parts. Capſule eight-celled, or ſometimes ten or eleven-celled. It is called *Hottentot's Figs*, being eaten by the Hottentots, and alſo by Dutch inhabitants of the Cape.

It rarely produces flowers, except from old plants. They appear in july [h].

Native of the Cape. Introduced in 1690, by Mr. Bentick [i].

49. This grows up into a long ſlender and not much branched ſhrub, from a foot to two feet high and more. Leaves ſlender, oblong, bluntly three-ſided, green not glaucous, rugged to the ſight, not the touch, with frequent green tubercles, which when held to the light appear whitiſh and pellucid. Similar tubercles are obſerved in the lower part of the fruit. Flowers terminating, middle-ſized, golden within, red on the outſide. Petals very many, narrow, entire, cuſped, nearly of the ſame ſize, the ends being tinged with a ſlight redneſs appear ſaffron-coloured. Stamens very many, at firſt leſs ſcattered, but when the petals are fully expanded, they are ſpread out upon them: the anthers are tinged with the ſame colour as the petals. Style divided into five ſhort villoſe ſegments [k].

Mr. Haworth makes two ſpecies of this, which he calls *bicolorum* and *coccineum*. He remarks that the firſt is at once known by its yellow flowers, and the ſecond by its deep orange-coloured ones. When paſt bloom, the unfertile bracteal leaves inveſting the pedunclies of coccineum, point it out from bicolorum, which has at that time conſiderable ſhoots in the axils of its uppermoſt leaves. Bicolorum has alſo a paler bark, longer and more rugged leaves, and the ſhoots are more robuſt. Coccineum has handſomer flowers, which in old plants are very numerous.

Native of the Cape. Cultivated in 1696, in the royal garden at Hampton Court. It flowers from may to ſeptember [l].

50. This is a ſhrubby plant, ſcarcely capable of ſupporting itſelf upright when tall. Branches woody, dark brown, ſlender, long, not crowded; the young ones ſomewhat compreſſed and greener. Leaves ſlightly glaucous, ſmooth, erect, between ſubtriquetrous and ſemicylindric, with acute points, which often aſſume a purpliſh tinge. Flowers large and ſpecious, of a very deep orange colour, opening very early in the morning if the ſun ſhines, remaining open only a ſhort time: quickly folding if the ſun diſappears, or if the plant be removed into the open air. Peduncles terminating and axillary, round, thickening upwards, but ſometimes not quite ſo thick cloſe to the calyx as a little below it. Calyx large; ſegments acute, nearly equal, more or leſs membranaceous and dotted. Petals numerous, long, linear but broadiſh, ſharpiſh, deep orange on the inſide, paler without, making a fine appearance when expanded. Filaments deep yellow, juſt ſhorter than the calyx. Germ ſmooth. Styles five-angled, or rather one ſtyle deeply divided into five ſegments or ſtigmas, which are black purple, ſpreading, fixed as it were to the ſtyle by an extremely ſhort ſlender thread, ſwelling out in the middle, and tapering obliquely towards the points, or rather gibbous awl-ſhaped, with a roughened ſurface. Capſule urn-ſhaped, ſlightly hollowed at the top, five angled, five-celled. Seeds rather few. It varies with paler flowers [m].

This is one of the taller and more upright ſpecies, as well as the earlieſt in point of flowering, producing its bloſſoms from february to may [n]: according to the Kew catalogue, from june to auguſt. Mr. Miller cultivated it in 1750 [o], but it does not appear in his Dictionary.

51. This is an elegant ſpecies, three quarters of a yard in height, with woody ſtems, not ſo thick as the little finger, and not much branched, procumbent, covered with an aſh-coloured bark. Flowers on the upper branches, ſolitary, terminating, large, of an elegant yellow colour, compoſed of two or three rows of petals, which are blunt, entire or ſometimes jagged, the outer longer and flat, the inner ſuddenly ſhorter, more erect, concave, and at their baſe a circle of ſaffron-coloured anthers on very ſhort filaments; the bottom of the flower being void, ſmooth and even, hollowed out like a diſh. They open ſeveral times from eight in the morning to three or four in the afternoon, if the ſun ſhines; and have a little ſmell.

Calycine ſegments long, mucronate, with a few ſerratures on the back; three longer, two ſhorter, having a pellucid membrane towards the baſe ſpotted with red. The calyx, and leaves about the edges, when held up to the ſun appear to have large white dots. The leaves, except thoſe on the flowering branches, come out ſeveral together, are long and pointed, deeply ſerrate on the back only, ſeldom on the edges; they are of a green glaucous colour. The branches, eſpecially the flowering ones are round only ſlightly compreſſed at the edges, aſh-coloured at bottom, next the flowers pale green, or elegantly purple. Capſules large, flatted at top, purple, five-angled, with a five-cleft ſtar, the reſidue of the ſtyle, in the centre, winged by five lines which deſcend along the peduncles to the very branches: cells five, large, with large roundiſh-flatted ſeeds in them [p].

Native of the Cape. Petiver received it in flower, in june 1706, from the Temple Garden. Dillenius received it from Holland before 1732, and gives a caution conſtantly to raiſe young plants, becauſe the old ones are very apt to periſh. It is probably for want of attending to this caution, that the ſpecies is now ſo rare in this country, if indeed it be in any of our collections.

52. Stems from a foot to two feet in height, procumbent, woody and much branched. Branches round, ſlender. Leaves in pairs, at an inch or an inch and half diſtance, an inch in length, thickiſh, on an old plant narrower and ſhorter, on a young one longer and thicker, not quite round, but obtuſely triangular, with the angles however ſo blunt, that they are rather cylindric than three-ſided: they are overſpread with glittering ſpangles of a greeniſh yellow colour. The ſtems and lower branches are bay-coloured and ſmooth; the upper ones are reddiſh brown, rough to the touch, with many whitiſh dots, which were originally ſpangles: the pedunckes and calyxes ſhine with ſpangles like thoſe of the leaves, but thicker. Flowers terminating, on pedunckes from an inch to an inch and half in length; they are large, concave, with the margin bent back, compoſed of numerous petals cohering at the baſe, gradually ſmaller, and filamentoſe in the middle, of a dirty red colour on the outſide, but within very dark orange-coloured, deepeſt at the edge; the narrow middle petals next the white filaments being very dark, this flower is eaſily diſtinguiſhed from the other ſorts by this circumſtance. Filaments ſhort, neither ſpreading, nor collected into a bottle. Style villoſe. Calycine ſegments often reflex and hooked, and having a thin pellucid membrane about the edge. Capſule

[f] Haworth. [g] Linn. [h] Dillenius. [i] Hort. kew. [k] Dillenius. [l] Hort. kew. [m] Haworth. [n] Curtis. [o] Hort. kew. [p] Dillenius.

small, depressed, with five prominent rays and as many cells [1].

It varies with paler, smaller flowers [2].

Native of the Cape. Cultivated in 1716, by Professor Richard Bradley. It flowers from may to august [3].

53. Native of the Cape, where it was found by Masson, and introduced in 1774. It flowers from august to october [4].

54. This is a branching divaricating shrub [5], found also by Masson at the Cape, and introduced at the same time with the preceding. It flowers in july and august [6].

55. This is a stemless plant, producing offsets, which when the old leaves that enveloped them decay, appear like distinct plants. Leaves connate for half an inch or an inch at the base, spreading, glaucous green, dotted, semicylindric, awl-shaped; or, convex on the outside, flat on the inside, usually but not always triquetrous at the points, generally about two inches and a half or three inches long, but sometimes longer [7].

Dillenius remarks, that this species is distinguished from all others by the central leaves being long and narrow, not ill representing a heron's bill.

Native of the Cape. Cultivated in 1732, by James Sherard, M. D.

56. Native of the Cape, where it was found by Mr. William Paterson. Introduced in 1780 by the Countess of Strathmore. It flowers in november [8].

57. Stem woody, from a foot to two feet in height, covered with an ash-coloured bark, deformed by age with irregular wide fissures, knotted and jointed, divided and subdivided into several opposite branches. Leaves so bluntly triangular as to appear to be round, an inch and half or two inches in length, the size of a swan's quill, with dense bundles of other leaves coming out from the axils, glaucous, smooth, appearing pellucid when held up to the light, purple at the end as are also the branches. Branches and leaves at short intervals, and affecting an upright position this plant has the appearance of a shrub, though probably it would be weighed down by the number and size of the leaves and branches. Flowers in a sort of umbel at the ends of the branches from the axils of the leaves, small, pale yellow. Petals broadish, blunt, entire, equal, spreading out regularly. Capsule turbinate, commonly five-celled but sometimes divided into more parts. Seeds rather large, three-sided, rufous.

It varies with shorter and more manifestly three-sided leaves and fewer flowers [9].

Linnæus remarks, that the flowers smell very sweet, that the corolla is scarcely longer than the calyx, with the petals having one or two teeth at the end, and the stamens small, with the filaments villose at the base.

Native of the Cape. Cultivated in 1732, by James Sherard, M. D. It flowers in may and june [10].

58. This is a shrub variously branched. Branches usually opposite, but sometimes alternate, axillary; at first herbaceous, compressed or ancipital and spreading, afterwards becoming rounded and more horizontal, finally quite round; woody, firm, and covered with a loose brown bark. Leaves almost upright when young, spreading when full grown, and often reflected when old; scarcely connate when young, slightly connate when old; of a very dull glaucous colour, or rather somewhat hoary and soft to the touch, with a thickish skin, very turgid on all sides, but most so above, with very blunt angles, marked by moniliform lines of semitransparent or lucid contiguous punctures; they are blunt with a fine white almost imperceptible point, best observed on the youngest leaves [11].

Native of the Cape, where it was found by Masson. Introduced in 1774 [12].

59. Stems half a yard high and more, woody, with frequent joints, ash-coloured with fissures at bottom, bay-coloured and more smooth above. The lower and middle branches are twisted, the upper ones are straight and little divided. Peduncles an inch and half or two inches long. Flowers large, pale yellow or sulphur-coloured on both sides, sometimes slightly tinged with red on the outside. Petals long, narrow, cuspid, with smaller ones interspersed among the others. They remain expanded only a few hours, and contract about noon: but open several times, and have a succession during the summer months. Style, filaments and anthers of the same colour with the corolla. Capsules small, bluntly turbinate. Seeds small, dusky yellow. Leaves glaucous, roughish and wrinkled, with frequent tubercles, which appear to be pellucid dots when held up to the light [13].

Mr. Haworth remarks, that it is a strong upright shrub, and that the flowers are produced only by old plants, and by them sparingly.

Native of the Cape. Cultivated *1696*, in the royal garden at Hampton Court. It flowers in june and july [14].

60. Dillenius, comparing this with variety β, says that the stems are longer, less pressed to the ground, all the leaves at the joints are very long, more thick and glaucous; the peduncles not naked but surrounded by a pair of short leaves; the flower of a deeper yellow colour, with a red line along the back; in β this inclines more to purple, and shines through the tips of the petals. Stamens numerous, neither collected nor much scattered, yellowish with whitish anthers. Styles very many, (Linnæus says ten) reddish, slender, villose. Capsules round, depressed, fifteen or sixteen-celled, with a crown on the top of the same number of rays. The leaves which spring from the axils of the larger ones are less frequent, and less bent in: but these younger leaves have the angles more acute and are more glaucous than the longer leaves at the joints, which the nearer they are to the root, the paler and more flaccid they seem to be, the rest are more rigid and succulent, not wrinkled and scarcely dotted, but the lower ones have transverse lines on their flat sides, are somewhat wrinkled, and much dotted underneath. The flowers continue some days and expand about noon: they are flat, the size of those of Dandelion: petals cuspid, the inner ones somewhat shorter but fewer. Stems half-erect or reclining, scattered, round at top, striated and somewhat angular at bottom, woody, a palm or a long span in length, not much branched, nor throwing out roots at the joints.

β. This throws out many procumbent branches, tough at the lower part, but not properly woody, herbaceous at the upper part, about three inches in length, round or slightly angular, jointed at short intervals, with bluntly triangular leaves, from which other leaves spring in bundles, of the same form but shorter, the root-leaves and those at the base of the branches are remarkably long. The leaves bend like the horns of kine, whence the trivial name; they are somewhat glaucous, become soft and flaccid, and then appear marked with many lines and dots. Peduncles six inches in length or nearly so and naked. Flowers the size and almost the form of those of Dandelion, but paler or sulphur-coloured, composed of numerous petals of which the inner ones are shorter, with a red purple streak running along the middle on the outside, the same tinge appears at the extremity and base of the petals. Stamens numerous with yellow anthers. Style villose, many-cleft. Capsule compressed, many-celled. The flowers open about noon, but do not appear very often [15].

Native of the Cape. It flowered in the Elham garden in 1726.

61. Root annual, not much branched, of short duration. The whole plant is sprinkled over with glittering particles, like the Ice plant, to which it bears some affinity in its duration [16]. Stems branching, of a bright red colour, trailing. Leaves yellowish green, opposite, attenuated at the base. Flowers small, axillary, solitary, on longish peduncles, yellow. Calycine segments unequal, three being short, two longer and broader. Petals numerous, scarcely equal to the longest

[1] Dillenius. [2] Haworth. [3] Hort. kew. [4] Idem. [5] Haworth. [6] Hort. kew. [7] Haworth. [8] Hort. kew. [9] Dillenius. [10] Hort. kew. [11] Haworth. [12] Hort. kew. [13] Dillenius. [14] Hort. kew. [15] Dillenius. [16] Curtis.

segments of the calyx, linear, expanding in the afternoon. Filaments numerous, yellow. Anthers yellow. Germ roundiſh. Capſule obtuſe-angled, obtruncate. Seeds numerous, ſmall, roundiſh, brown[1].

Introduced from the Cape by Maſſon in 1774. It flowers in july and auguſt[2]. It was cultivated earlier in the botanic garden at Upſal, where it was probably introduced by Thunberg.

62. Native of the Cape, where it was found by Maſſon, and introduced in 1774. It is an annual, and flowers in july[1].

63. Stem ſhort, thickiſh. Branches unequal, ſpreading irregularly on the ground, covered with a ſmooth bark of a duſky yellowiſh colour, with other ſmaller ſimple ones ſpringing from them, which are alſo irregular and twiſted. Leaves pointed, ſlightly excavated within in the middle, the outer part produced and ſwelling, of a yellowiſh green colour, with frequent minute dots regularly in lines. Compared with M. expanſum, the flowers are ſomewhat ſmaller and whiter, petals narrower, peduncles ſhorter, ſo that the flowers frequently ſcarce emerge from the bundles of leaves. They are filamentoſe, and where they are white, ſhine with a ſilvery brightneſs in the ſun; but in the middle, next the ſtamens, they are ſlightly tinged with yellow and ſhine leſs. They are without ſcent, open two or three times, and in the day time only. Two of the calycine leaflets are larger, three ſmaller, and of theſe one is very ſmall. Capſule oblong-rounded, contracted into a neck about the calyx, with minute ſilvery tubercles on the ſurface, ſhining in the ſun; within four-celled[2].

Linnæus remarks, that three leaflets of the calyx are ſpreading, and two horned; that the corolla is ſhorter than the calyx; and that it has four ſtyles.

Mr. Haworth obſerves, that the young leaves, when juſt beginning to ſeparate, have a very ſtriking reſemblance to the beak of a bird.

Native of the Cape. Cultivated in 1705, by Dr. Uvedale. It flowers from june to october[3].

64. Found by Maſſon at the Cape, and introduced in 1787. It is an annual and flowers in july. Theſe annuals are very ſubject to be loſt in our gardens.

65. This is another annual, introduced by Maſſon from the Cape, in 1774. It flowers in july and auguſt[2].

66. Root annual. Stem herbaceous, a ſpan high, ſcarcely thicker than a gooſe quill, almoſt upright, round, rough with cluſtered reflex or ſpreading white hairs. Branches oppoſite, almoſt upright, higher than the ſtem, dichotomous. Leaves oppoſite, horizontal, embracing, quite entire, blunt, very ſmooth, ciliate eſpecially at the baſe, where they are alſo channelled. Peduncles from the forks, ſolitary, round, upright, rough with very ſpreading hairs, the length of the leaves, one-flowered. Flowers upright, the ſize of the common Marygold. Calyx very large, rough with white hairs; ſegments ſpreading, unequal: two longer than the corolla, lanceolate, flat, hairy within at the baſe; three the length of the corolla, ſubcylindric, membranaceous within towards the baſe. Corolla ſulphur-coloured, ſtarting, ſpreading very much. Petals very numerous, in ſeveral rows, the inner ones gradually ſmaller, linear-ſubulate, the inmoſt briſtle-ſhaped, curved inwards, covering the ſtamens, from which indeed they differ only in being deſtitute of anthers. Filaments yellow, in a cylinder, covering the piſtils. Anthers nodding, oblong, yellow. Germ depreſſed, ſmooth, with from twelve to fifteen ſtreaks. Styles twelve to fifteen, upright, ſpreading at top. Capſule orbicular, flatiſh, many-celled. Seeds ſemi-orbicular, compreſſed, black, ſmooth, ſmall.—It is diſtinguiſhed by the number of piſtils and cells[3].

Native of the Cape. Introduced in 1774, by Mr. Francis Maſſon. It flowers in july and auguſt[2].

67. a. Mr. Haworth remarks, that the calycine leaves are proportionally larger than thoſe of the white-flowered one. The juicy leaves, and more particularly the flowers, when bruiſed, ſtain paper a ſtrong yellow colour.

β. This is a diffuſe, ſhrubby plant. Branches cylindrical, axillary, long, at firſt upright, afterwards declining and very diffuſe, ſometimes covered thinly with briſtly hairs, for the moſt part only with numerous roughiſh papulæ, which are greeniſh on the young ſhoots, and white on the old ones. Leaves very groſs, diſtinct, ſpreading, convex beneath, concave above, echinate or furniſhed on every part with ſtraight ſtrong white hairs or briſtles, which ariſe from large papuloſe dots, are nearly upright, and ſometimes hooked. The young leaves, when the plant is drawn up in a ſtove, ſometimes become entirely ſmooth, and ſmaller than uſual, but even in this ſtate the roughened or warted branchlets diſtinguiſh it from M. barbatum. Peduncles axillary, ſhort, one or more from the ſame place, ſometimes hiſpid, ſometimes not. Calycine ſegments unequal, three long and reſembling the leaves on the branches, two very ſhort with membranaceous edges, all more or leſs echinate with ſhort white briſtly hairs. Flowers pretty numerous, ſmall, opening in the fore part of the day, white. Petals linear, obtuſe, entire, very little longer than the leaves of the calyx. Filaments numerous, ſlender, often echinate with ſhort hairs, attached to the petals below, and converging above. Anthers very minute, yellow, ovate, with a groove on one ſide, fixed to the filaments by their ſides, but towards the top: pollen deep yellow. Germ nearly hemiſpherical, or approaching to conical, with a hollow or navel at top, ſmooth, ſhining, with five ſmoothiſh angles. Styles yellow, ſpreading, united below, and occupying the navel on the crown of the germ. Capſule five-angled, five-celled[4].

Native of the Cape, where it was found by Maſſon. Introduced in 1774. It flowers from july to october[3].

68. a. Dog-chap Fig Marigold is ſtemleſs whilſt young, but requires by age conſiderable traiſing woody ſtems. Leaves connate, ſpreading, glaucous, opaque not marked with lucid dots, ſomewhat ſabre-ſhaped, or attenuate from the middle downwards to the baſe, where they are ſemicylindric; thickening towards the points, where they are triquetrous, with a ſharp keel, and ſides edged with irregular harmleſs teeth; terminating in a ſimilar tooth, placed on the inner ſide. Flowers large, ſhowy, yellow, opening in the afternoon, and cloſing in the evening. Peduncles often furniſhed with connate bractes, long, terminating, uſually three, the middlemoſt often longeſt, cylindrical upwards, often nearly ancipital and thickened. The two outer calycine ſegments are rather longer than the three inner, which are blunter and membranaceous. Petals bright ſhining yellow within, often tinged with purple on the outſide, numerous, linear, not very blunt, entire. Filaments numerous, whitiſh yellow. Anthers deep yellow. Styles ſtraight, as long as or longer than the ſtamens, greeniſh yellow[1].

β. Cat-chap Fig-Marigold is entirely ſeſſile, of a whitiſh glaucous colour, with the leaves paler at the baſe, with frequent round whitiſh dots, eſpecially towards the end; they are ſhorter than thoſe of the preceding, more reſupine, leſs triquetrous, but with a rounder back, and more frequent, longer, incurved prickles, terminated by ſlender harmleſs ſpinules, which are ſometimes white, ſometimes reddiſh; the leaves have a white line at the end, which is continued towards the back. There is firſt a flower in the middle, and afterwards ſeveral come out ſucceſſively at the ſides, all ſeſſile. Calyx five-angled; ſegments two broader and three narrower. Corolla golden-coloured within, not having any tinge of red, yellow with a tinge of red on the outſide; petals in three or four rows, entire, cuſped; the inner ones ſomewhat ſmaller. Stamens numerous, more ſcattered than in the preceding. Capſule round, ſeſſile, with a browniſh circle at top, in the centre of which are veſtiges of the ſtyles, and in the circuit three green riſings[4].

According

According to Mr. Haworth, the plant is leſs and ſofter to the touch than the preceding variety, and is completely ſtemleſs in all ſtages of its growth. Leaves ſhorter, dotted, much ſofter to the touch, and of a laxer ſtructure, rounded or blunt on the keel, and not acutely triquetrous upwards, as in caninum; edged above with long harmleſs ſpinuloſe hairs or teeth, not with ſhort fleſhy denticulations, as in caninum.

Mr. Haworth adds two other varieties, and he regards them all as ſpecies.

γ. M. tigrinum. Tiger-chap Fig-Marigold, is ſtemleſs in all its ſtages of growth; it is more ſucculent and groſs than ſeſinum. Leaves rather ſhorter, beſet with much longer hairs on the ſides, and having numerous whitiſh ſpots. Flowers ſeſſile, yellow, large.

δ. M. murinum or Mouſe-chap Fig-Marigold. In this the branches in very old plants are ſome inches long and numerous, forming a fine tufted plant. Leaves connate, when young reſembling the gaping jaws of a ſmall quadruped, the denticulations on each ſide reſembling teeth; when old, the leaves ſpread out and are even recurved; all are very glaucous, only about a fourth part of the ſize of the others, and often roughly dotted: dots lucid, elevated into ſmall tubercles. Flowers ſmall and yellow[a].

Natives of the Cape. Dog-chap Fig-Marigold was cultivated in 1717, and Cat-chap about the ſame time. They flower from may to july.

69. At firſt this is a low plant, but it becomes larger and ſtronger, it does not however riſe above a long ſpan in height in ſix years: the ſtem is then thick and woody, and ſeveral reclining twiſted branches ſpring from it alternately, covered with a duſky reddiſh bark, ſmooth but tranſverſely chinked and irregular; at the end of which come out ſeveral leaves diſpoſed croſswiſe; they are thickiſh, bluntly flat at top, with a roundiſh back below, more compreſſed towards the end, and terminating in a proceſs at the lower part; their colour is deep glaucous green, except the old ones, which are yellowiſh and when dry brown: the whole covered with frequent green dots, pellucid when held up to the light, protuberant towards the end of the leaves and rendering them ſomewhat rugged there. Peduncles an inch and half or two inches long, bracted. Flowers opening in the afternoon, (about four o'clock) like M. ringens caninum, and like that coming out frequently ſeveral from the ſame peduncle, but they are much ſmaller and of a paler yellow colour. Petals many, narrow, cuſped, the outer more ſpreading, the inner more upright, at firſt forming a concave flower, but afterwards more flat and ſcattered, pale red on the outſide. Stamens upright, with thickiſh, cylindric anthers. Calycine ſegments equal, at firſt upright, but afterwards bent down, and then becoming upright again. The flowers keep open a great part, if not the whole of the night. Capſules ſmall round-five-angled, each angle roundiſh, with a ſtreak along the middle, five-celled. Seeds ſmall, like ſand[a].

Native of the Cape. Cultivated in 1714 by the Dutcheſs of Beaufort. It flowers from may to july[a].

70. This is a middle ſort between the caulescent and ſeſſile ones, properly belonging to thoſe which are procumbent, and acquiring by age woody branches, ſhort and preſſed to the ground, from which, at ſhort diſtances, and on ſhort ſlender woody petioles, of a duſky pale brown colour, ſpring thick leaves in cluſters, bright green and ſhining, triquetrous inclining to round, wider towards the baſe and ſomewhat flatted on the upper part, the lower part rounded, towards the middle where the flat part ends, ſome ſhort proceſſes come out on both ſides, ſometimes on one ſide only, and ſometimes they are wholly wanting; hence towards the point the leaves take a different form, and have the ſides from round flatted; they are not however broad and flat, but triquetrous-cylindric. It is a circumſtance peculiar to theſe leaves, that one ſide of each is much ſhorter than the other, and hence they are called diſform: they have frequent largiſh dots on them, which appear pale and pellucid, but ſometimes duſky green; they are generally protuberant and thereby render the ſurface irregular. Peduncles thick, herbaceous, bluntly triquetrous from half an inch to an inch and half in length. Flowers rather large, like thoſe of the tongue-leaved ſort, but ſomewhat ſmaller, and of a deeper yellow, internally they are of a ſhining golden colour, externally of a reddiſh ſaffron colour, and when far advanced they are ſaffron-coloured within. Petals oblong, blunt, entire, not ſo numerous as in ſome ſorts, in a ſingle or double row. Stamens very many, pale yellow. Styles many (eight or thereabouts) ſhort, cirrhoſe, greeniſh yellow. Capſule eight-celled. Seeds triquetrous, brown and wrinkled.

Native of the Cape. Cultivated in the Eltham garden ſeveral years before 1732, loſt by the ſeverity of a winter, and recovered there from the botanic garden at Chelſea[a].

71. Lower leaves oblique, the others more upright, not at all or but little bent in or ſickle-ſhaped; they are long, thick, rigid, ſmooth and ſhining, flat within or on the top, underneath produced into a ſharpiſh back, which becomes blunter and rounder in the lower part; all the ſides are nearly equal: they are of a white elegantly glaucous colour, except that they are yellowiſh near the baſe with ſlender tranſverſe lines. Flowers large, yellow, on a long thick peduncle. It flowered many years before 1732, and frequently in the Chelſea garden during winter[a]. According to the Kew catalogue it was cultivated in 1714, by the Dutcheſs of Beaufort.

72. The leaves of this ſpecies in all the varieties are not decuſſated, but lie in the ſame oblique plane. α. The leaves of this are wider and more compreſſed about the edge; the flowers ſomewhat larger, with blunter petals, more ſcattered and leſs numerous, with ſcarcely any peduncle. One plant has ſeveral heads, from each of which are produced cluſters of leaves in pairs, diſpoſed like thoſe of the tongue Aloes, but with the edges not horizontal but oblique. There are generally three or four pairs of theſe leaves; they are broad and thick, flat above, pillowed below, bright green, ſmooth and ſhining, ſometimes blunt, ſometimes a little pointed, generally in the ſhape of a ſhoemaker's knife. The younger leaves in this and the other varieties are folded together and obliquely inſerted into each other. The flowers come out ſucceſſively in auguſt and ſeptember from the axils, beginning with the loweſt, they are ſubſeſſile, large, yellow, ſomewhat paler than in the next variety, ſhining in the ſun; petals ſomewhat blunter, entire or ſometimes cut here and there. Stamens numerous, with oblong yellow anthers. Style divided into nine or eleven villoſe ſtigmas. Capſule roundiſh, divided into as many cells, with a crown at top of nine or eleven rays. Seeds like ſand, from round pointed. Calyx of four unequal ſegments, two longer and two ſhorter.

β. Broad Tongue-leaved Fig Marigold, has thick leaves, flat above, convex beneath, with the margins thicker and leſs upright than in the preceding, ſmooth and ſhining, pale green eſpecially towards the baſe, when held up to the light appearing to be compoſed of innumerable veſicles. Three or four pairs of theſe leaves lie in the ſame inclined plane; theſe are ſometimes flatter and blunt at the end, ſometimes very much cut at the edge. From the lower pair firſt, and then from the next, a ſhort peduncle ariſes, obtuſely triquetrous, bearing a large flower of a ſhining golden colour, with many ſtamens, having oblong golden anthers. Style divided into nine or ten cirrhoſe parts. Calycine ſegments four, ſometimes five. Capſules roundiſh, divided into nine or ten cells, continuing the whole winter, and ripening in the ſpring; they are obtuſely pyramidal and brownish. Seeds very many, like ſand, rufous, pointed, bluntly triquetrous.

γ. Narrow Tongue-leaved Fig Marigold is very like the preceding, but the petals have a ſlight tinge of red on the outſide, the older leaves are more reflex, the younger ones, which are cloſer and more luxuriant, are ſomewhat twiſted in and excavated, and are of a fuller green colour. The fruit is ſmaller and ſofter.

[a] Haworth. [a] Dillenius. [a] Hort. kew. [a] Dillenius. [a] Idem.

not elevated but rather depreſſed, roundiſh, and commonly ſtreaked with eleven angles; it is generally eleven-celled; the cells being the ſame in number as there are horns of the ſtyle, which are depreſſed at the bottom of the flower under the ſtamens, and are curled and wrinkled. Petals in two or three rows, almoſt of the ſame length, of a ſhining yellow colour. Stamens numerous, ſlender. Calycine ſegments uſually four. Peduncle an inch long, ſomewhat longer, than in the preceding, flat on one ſide, raiſed into an angle on the other, triquetrous-compreſſed, pale green. It flowers in auguſt and ſeptember.

β. This is diſtinguiſhed from the others by the leaves being longer and more erect. The peduncles of the flowers are longer. Capſules leſs globular, commonly divided into nine cells. Calycine ſegments four, three longer and narrower, one ſhorter and broader with a membranaceous margin. The flowers have a double or triple row of petals, ſhining in the ſun with the ſplendour of gold. Stamens numerous with oblong ſaffron-coloured anthers [c].

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort [d].

73. This ſpecies grows up into a ſtem an inch and more in thickneſs, and two or three feet in height, ſtanding upright with little or no aſſiſtance, with a crown of cluſtered leaves a long ſpan in length at the top, and branches a foot long and more at the baſe, which hang down with the weight of a multitude of leaves. Very old plants grow a yard in height, with long incurved twiſted branches. The ſtems and lower branches are of a duſky yelloviſh colour, but the upper flowering branches are green; on the lower part of theſe the leaves are alternate, but on the upper part, where the flowers come out, they are cluſtered and ſomewhat ſhorter, in pairs at ſhort intervals, triquetrous, with equal angles, ſlightly grooved on the ſides, eſpecially on the inner ſide; but the alternate ones have the inner ſide rather flat. They are not dotted, but are of a deep green, almoſt glaucous, like the leaves of Pinks, at the angles towards the baſe tinged ſlightly with purple. Peduncles from the axils of the upper leaves a ſpan in length, thick, at firſt hanging down, but afterwards erect. Flowers large, expanding when the ſun ſhines, ſtraw-coloured above, tinged with red underneath, compoſed of numerous ſlender cuſped petals, gradually ſmaller and the inner ones filamentoſe. Style divided into ten parts, concealed at firſt by the ſtamens, which on the ſecond or third expanſion of the flowers, recede from each other and leave the ſtyles naked. Capſule obtuſely conical, the ſize of a nutmeg, marked with fifteen lines, ten-celled. Seeds ſmall, roundiſh, pointed, rufous: when ripe, the upper fungoſe part opens into a toothed crown, the rays or toothlets and holes of which are the ſame in number as the lines on the fruit: but before the fruit is reſolved into this toothletted crown, the lines become as many furrows as there are cells. Calyx entire at the baſe, divided above into five oblong ſegments, broad at the baſe, triquetrous-cylindric; at bottom a rib runs from each of the wider ſegments along the peduncle, which has a pair of leaves near the baſe. The flowers are open from eight or nine in the morning to four or five in the afternoon [e].

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from may to auguſt [f].

74. Plant ſomewhat below, covered with a grayiſh bark. Branches moſtly oppoſite, axillary, decumbent; whilſt young ſmooth and papuloſe below, covered higher up with pileſcent papulæ, and at the uppermoſt parts with ſhort numerous horizontal hairs. Leaves dark green, connate, ſheathing, very blunt, channelled above, rounded beneath; lower ones erect, incurved, imbricate, croſſing each other in pairs, ſhining, ſmooth, papuloſe, reſembling the links of a chain; upper ones ſpreading more and more diſtant, pointing obliquely upwards, ciliate at the baſe with pileſcent papulæ; uppermoſt often alternate, covered with the ſame papulæ. Flowers terminating, from one to five, when three or four forming a ſmall dichotomous panicle; when five forming a kind of ſpike, curving ſharply upwards; they are the ſize of a ſhilling, quite green, and open in the forenoon. Peduncles cylindrical, covered with numerous ſhort horizontal hairs. Calyx ovate, obſcurely pentangular, ſegments unequal, two longer, the three ſhorter membranaceous on the edges. Petals very numerous, ſlender as briſtles, acute, innermoſt ſhorteſt, often converging ſo as to conceal the ſtamens. Filaments numerous, very ſhort, of different lengths, whitiſh green. Anthers large, white, nearly ſquare, emarginate at both ends, with a deep furrow on each ſide, giving them a twin appearance: pollen whitiſh. Styles ſhortiſh, green, awl-ſhaped. Capſule turn-ſhaped, pentangular. Seeds not very numerous, ſmall, kidney-ſhaped [g].

Native of the Cape, where it was found by Maſſon. Introduced in 1774. It flowers in july and auguſt [h].

75. Native of the Cape of Good Hope, where it was found by Thunberg [i].

There are doubtleſs many other ſpecies, but not being ſufficiently determined, or diſtinguiſhed from varieties, I have confined myſelf chiefly to thoſe which are aſcertained by Dillenius, Linnæus, and Aiton.

There are ſeveral circumſtances which may aſſiſt us in diſtinguiſhing the numerous ſpecies of this genus. Thus ſome are annual, though the far greater part of them be perennial. Some are ſtemleſs, as *ringens*, *bellidiflorum*, *linguiforme*, *albidum*, *roſtratum*, *calamiforme*, *difforme*, *dolabriforme*. Some are lax with a pendulous ſtem or branches, as *Tripolium*, *tortuoſum*, *expanſum*, *loreum*, *cornuculatum*, *acinaciforme*, *edule*, *forficatum*, *flamentoſum*, *craſſifolium*, *tenuifolium*, *pomeridianum*. The reſt are ſhrubby, with a woody hard ſtem. The greater part has oppoſite leaves, but ſome have them alternate, as *nodiflorum*, *cryſtallinum*, *Tripolium*, *purpuriformes*. Moſt of them have five ſtyles, but ſome have four, others ten [k], and the number varies in ſeveral of the ſpecies. Spinoſum (n. 32.) has trichotomous thorns; and tuberoſum (n. 33.) has a tuberous root.

This beautiful genus was firſt named *Ficoides* by Hermann, from the ſimilitude of the fruit in ſhape to the Indian Fig. Breynius, ſoon after named it *Meſembrianthemum* or Noon-flower, becauſe moſt of the flowers open about noon when the ſun ſhines. Dillenius changed Breynius's name to *Meſembryanthemum*, ſignifying a plant which has the embryo in the middle of the flower. Linnæus has followed Dillenius in this, although the change, in my opinion, is by no means a happy one. Dillenius however has treated this genus in his maſterly ſtyle, and Linnæus has added little or nothing to what he had done.

Dillenius diſtinguiſhes the ſpecies from the leaves, and has given a ſynoptical table of thoſe which he cultivated in Dr. Sherard's garden at Eltham. He remarks, that the corolla grows above or rather round the fruit, and may be extracted entire in ſome of the ſpecies; but in the greater part, eſpecially thoſe which have filamentoſe flowers, it adheres ſo firmly to the top of the fruit and the middle of the ſtyle, that it cannot be extracted entire: that the petals, or ſegments of the corolla are either leſs numerous and all nearly of the ſame ſize and form, or more numerous and of different ſizes, the interior ones being narrow like the filaments. The fruit is at firſt green, thick and ſucculent, but when ripe contracts, and becomes a fungous dry browniſh ſubſtance, of a turbinate, globular or oblate ſpheroidal form, ſometimes with a ſmooth and regular ſurface, ſometimes more or leſs angular. The number of cells within correſpond with the number of ſtyles, but not with the leaflets of the calyx, except in the four and five-celled ſpecies. In thoſe which are many-celled, the number of ſegments in the calyx is ſeldom more than five; and in M. linguiforme, which has more cells than five, the calyx has only four ſegments.

[a] Dillenius. [b] Hort. kew. [c] Dillenius. [d] Hort. kew. [e] Haworth. [f] Hort. kew. [g] Linn. ſuppl. [h] Hort. kew. [i] Linn. ſpec. [k] Hermann.

Hermann, in his different works, has enumerated twenty-three ſpecies, two of which do not ſeem to belong to this genus. Breynius has ſeventeen ſpecies. Plukenet has forty-four. Bobart has fifteen. J. G. Volckamer has twenty-four. Ray has thirty-nine, but ſome of the ſpecies are repeated under different names. Tournefort has thirty-ſix, in the Paris Memoirs. Bradley figured thirty ſpecies. Boerhaave enumerated fifty-three, but his two laſt do not appertain to this genus. Dillenius has deſcribed and figured fifty-ſeven, ſome of which however are varieties. Miller, in the laſt folio and quarto editions of his Dictionary has enumerated forty-ſix: but he has not deſcribed any of them. Aiton's Catalogue of the Royal Garden at Kew contains ſeventy, and this work ſeventy-five ſpecies. Mr. Haworth has many more, ſome of which however are ſtill regarded by botaniſts as varieties only, though they are ſold by nurſery-men as diſtinct ſpecies.

PROPAGATION AND CULTURE.

This fine genus was unknown to the ancients, indeed very few of the ſpecies were cultivated till the end of the laſt and the beginning of the preſent century. M. edule was introduced in 1690, by Mr. Bentick from Holland, and in 1696 ſeveral of the ſpecies were cultivated in the royal garden at Hampton Court. Some were in the botanic garden of the Apothecaries at Cheliea in 1700. Dr. Uvedale and Charles Dubois, Eſq. had ſome ſpecies in 1705. The Dutcheſs of Beaufort had many in 1714. Profeſſor Bradley cultivated a good collection between 1716 and 1727. About the ſame time the Sherardian garden at Eltham boaſted a very fine aſſemblage of theſe ſingularly beautiful plants: and as many were cultivated by Mr. Miller at Chelſea. M. auſtrale was introduced from New Zealand, in 1773, by Sir Joſeph Banks. M. compactum, by the Counteſs of Strathmore 1780, and many ſpecies by Mr. Francis Maſſon in 1774, 1775 and 1787. The collections of theſe plants at Kew, Mr. Lee's nurſery at Hammerſmith, and ſeveral others of the nurſeries about London are very ſplendid.

The Ice plant (M. cryſtallinum) and other annual ſorts are propagated by ſeeds, ſown on a hot-bed early in the ſpring. When the plants come up, plant them on a freſh hot-bed to bring them forward. After they have taken root in the hot-bed they ſhould have very little water. When they are large enough to tranſplant again, plant each in a ſmall pot filled with light freſh earth, but not rich, and plunge them into a hot-bed of tan, ſhading them in the heat of the day until they have taken new root, and then giving them plenty of freſh air. At the end of june ſome of the plants may be inured to the open air, and afterwards may be turned out of the pots and planted in a warm border, where they will thrive and ſpread, but will not be very productive of flowers; ſome therefore muſt be continued in the pots, and removed to the ſhelves of the ſtove, that they may flower plentifully and produce good ſeeds.

The perennial ſorts are eaſily propagated by cuttings during any of the ſummer months; ſuch of them as have ſhrubby ſtalks and branches, very readily take root when planted in a bed of light ſoil, and covered either with mats or glaſſes; but when they are covered with the latter, they muſt be ſhaded every day when the ſun is warm; theſe cuttings of the ſhrubby ſorts need not be cut from the plant more than five or ſix days before they are planted, during which time they ſhould be laid in a dry room, not too much expoſed to the ſun, that the part which was ſeparated from the old plants may heal over and dry before they are planted, otherwiſe they are apt to rot; theſe may be planted at about three inches diſtance from each other, and the earth preſſed cloſe to them, but none of their leaves ſhould be buried in the ground, for as they abound with moiſture, if they are covered with the earth, it will cauſe them to rot, and that often deſtroys the cuttings; therefore when the cuttings are taken from the old plants, they ſhould be diveſted of their lower leaves, ſo far as may be neceſſary, to allow a naked ſtalk of ſufficient length for planting.

When the cuttings are planted, it will be neceſſary to give them a little water, to ſettle the ground about them, but it ſhould be done with caution, for too much wet will ſpoil them; if theſe are ſhaded every day from nine or ten o'clock till three or four, when the ſun is warm, it will prevent the ground from drying too faſt, ſo that the cutting need not be watered oftener than once in a week; but if there ſhould happen ſome gentle ſhowers of rain, it will be proper to take off their covers, and let them receive it, but they ſhould be ſereened from hard rains. The cuttings thus managed will have put out good roots in about ſix weeks, when they ſhould be carefully taken up, and each planted in a ſeparate ſmall pot filled with light ſandy earth, and then placed in a ſhady ſituation, giving them a little water to ſettle the earth to their roots; in this place they may remain about ten days or a fortnight, by which time they will have taken good root, and may be removed to a ſheltered place, where they may have more ſun, in which they may remain till autumn; during the ſummer months, theſe may be watered twice, or in very hot weather, three times a week, but it muſt not be given them in too great plenty; but as the ſun declines in autumn, they ſhould not have it oftener than once a week, for if they are often ſupplied with it, the plants will grow luxuriant; their leaves and branches will be ſo replete with moiſture, that the early froſts in the autumn will deſtroy them; whereas when they are kept dry, their growth will be ſtinted; ſo that they will be hardy enough to reſiſt ſmall froſts, but there muſt be care taken that they do not ſhoot their roots through the holes of the pots into the ground, for when they do, the plants will grow very luxuriant; and when the pots are removed, and thoſe roots are torn off, their leaves and branches will ſhrink, and will not recover in a long time, if ever; to prevent which, the pots ſhould be removed every fortnight, and where the roots are beginning to come through the pots, they ſhould be cut off. The ſorts which grow very freely ſhould be ſhifted three times in the ſummer, to pare off their roots, and keep them within compaſs, and theſe ſhould never be planted in rich earth for the reaſons before given; for if the earth be freſh, it will require no dung or other compoſt, unleſs it is ſtrong, in which caſe ſea ſand, or lime rubbiſh, will be a good mixture; the quantity of either muſt be in proportion to the ſtiffneſs of the ground, always being careful to render it ſo light, as that the wet may eaſily paſs off.

We next proceed to treat of thoſe ſorts, whoſe ſtalks and leaves are very ſucculent. The cuttings of theſe ſhould be taken from the plants ten days or a fortnight before they are planted, that they may have time for their wounded part to heal over and dry; the lower leaves of theſe ſhould alſo be ſtripped off, that their naked ſtalks may be of a ſufficient length for planting. As theſe are moſtly plants of humble growth, ſo if their ſtalks are diveſted of their leaves an inch and a half, it will be ſufficient. The cuttings of theſe ſorts require to be covered with glaſſes, to keep off the wet; they muſt alſo have leſs water than the other, but in other particulars require the ſame treatment. The roots of theſe not ſpreading and extending ſo much as thoſe of the other, will not require to be ſhifted oftener than twice a year at moſt; they muſt alſo be kept in ſmall pots to confine their roots; the earth in which they are planted ſhould be rather light and not rich. During the ſummer ſeaſon they muſt not have too much wet, and in the winter they muſt have but little water. If theſe ſucculent ſorts are placed in an open airy glaſs-caſe in winter, where they may have free air admitted to them in plenty in mild weather, and are ſcreened from the froſt, they will thrive much better than when they are more tenderly treated.

The other ſhrubby ſorts may be ſheltered in winter under a common frame, where, if they are protected from froſt and wet, it is all they require; for the hardier theſe are treated, the greater quantity of flowers they will produce: and ſome of the ſorts are ſo hardy, as to live abroad when planted cloſe to a good aſpected wall, and in a poor dry ſoil; ſo that where there is room to diſpoſe them again a wall, and the

border

border is raiſed with lime rubbiſh to prevent their rooting deep and growing luxuriant, they may be preſerved through the winter with very little ſhelter, and theſe will flower much better than thoſe under cover.

[The hardieſt ſorts are *biſpidum*, *ſtriatum*, *barbatum*, *craſſifolium*, *glaucum*, *uncinatum*, *corniculatum*. Theſe will ſometimes abide ſeveral winters, on a dry artificial rock, or upon the top, or at the foot of a dry wall.

Theſe plants thrive beſt in winter in a dry light airy ſtove or large glaſs caſe, not overſtocked with plants, eſpecially ſuch as cauſe watery vapours by caſting their leaves. The flues ſhould be gently worked in cold and damp weather, and the plants ſhould not be placed too near each other, ſhould have as much free air as poſſible when the weather is dry and favourable, and ſhould be watered only ſparingly in cold weather. Thoſe ſorts which hold water in the centre, ſhould not be watered over their tops in winter.

From about may to ſeptember all the ſorts thrive beſt in the open air, in a ſheltered warm ſunny ſituation, no more watered than juſt to preſerve their leaves from ſhrivelling. But if the ſeaſon be wet, it may be better to leave them in the houſe, which during this ſeaſon will be thin of plants and have the lights generally open.

The generality of ſpecies are beſt planted in ſmall pots, not larger than thirty-twos. They ſhould be filled with a light ſandy unmanured ſoil, that will not bind. The ſmalleſt ſorts thrive ſtill better in ſixtys.

All the perennial and ſhrubby ſorts may be increaſed very readily in a ſtove, either from ſeed or cuttings, not covered by bell-glaſſes. Sow the ſeed, as ſoon as procured, unleſs it be in the depth of winter, in a poor light ſandy ſoil, kept damp but not wet: its germination will be much aſſiſted by the bark-bed.

They all remain a long time in the ſeed leaf. When the young plants appear, they ſhould have rather more water and air, until they have four or five leaves, when they may be tranſplanted into the ſmalleſt pots, kept in the ſame gentle hot-bed until they have got freſh roots, when they ſhould be gradually hardened to the open air, if it be ſummer, or placed near the old plants in the dry ſtove, if it be winter. When they have filled the ſmall pots with their roots, they ſhould be removed into larger ones.

When raiſed from cuttings, the ſhoots need not be large, and the youngeſt are the beſt; they ſhould be divеſted of a few of the old leaves, and if very ſucculent, laid in a dry ſhady place, from one to twenty-four hours, to heal their wounds, after which plant them in the ſoil mentioned above, with the earth preſſed cloſe, water them very ſparingly, and ſhade them from the ſun until they have ſtruck root, but without covering them by a hand-glaſs. Their ſtriking will be greatly accelerated by plunging them into a gentle hot-bed; but moſt of the ſorts will ſucceed very well without that aſſiſtance, if kept in the houſe; and many will do well during the ſummer even in open borders, provided they are gently watered when dry.

May is the moſt favourable ſeaſon for ſtriking them; but they may be ſtruck at almoſt all times of the year in a very moderate ſtove. Some ſtrike in ten days, ſome take a fortnight, and others require a month or ſix weeks.

8. Strikes readily from young ſhoots, but with difficulty from old ones. It is apt to loſe its leaves, and then looks like a different plant.

20. M. cordifolium planted in a ſouth border will cover many feet of ground, flower and perfect ſeeds.

29. M. reptans, in the open air will extend its branches above a foot and half every way, putting out roots at every joint.

39. M. craſſifolium. This and many others, particularly the creeping and procumbent ſorts, may be ſtruck from the extreme ſhoots, although they have only two leaves.

42. The old firm ſhoots are ſtruck with difficulty from cuttings, but the young and tender ones moſt readily.

48. M. edule. A ſingle joint will ſtrike very well in any way.

61. M. pinnatifidum, cannot be made to root from cuttings, which however do not die until they have perfected flowers, and even ripened ſeed.

67. The old wiry firm ſhoots ſtrike with difficulty from cuttings, but are ſo tenacious of life as to exiſt a whole year without loſing their leaves. The young ſhoots ſtrike freely.

68 β. M. ringens ſelinum may be ſtruck from a ſingle leaf.

71. M. albidum does not root ſo freely from cuttings as the other ſtemleſs ſpecies, eſpecially from an old plant. The reaſon is, that it is of a very firm texture, and it is a general rule that ſuch ſtrike with difficulty, and thoſe of a more lax ſucculent nature on the contrary ſtrike with facility.

73. M. pugioniforme. Cuttings of this ſtrike with difficulty. It very much diſlikes the knife. Select ſmall ſhoots, ſeparate them with a ſharp knife, bruiſe or handle them as little as poſſible, plant them in a mixture of light earth and pottherds, keep them in a ſtove in the ſhade, and water them ſparingly. It frequently perfects very fine ſeeds, by which it may readily be increaſed[1].

MESOSPHÆRUM. See *Byſtropogon*.]

MESPILUS (*of Pliny*, Μεσπιλον *of Theophraſtus.*)

Lin. gen. n. 625. *Reich. n.* 681. *Schreb. n.* 857. *Tourn. t.* 410. *Juſſ.* 335. *Gærtn. t.* 87.

DESCRIPTIONS, *&c.*

1. This is a buſhy irregular ſhrub. Branches ſtrigoſe and rugged, teſtaceous-brown, divaricated, alternately ſpinoſe. Spines axillary, commonly branched with ſecondary ſpines, ſometimes gemmiferous and producing branchlets. Leaves ſcattered ſmooth, petioled, continuing till winter, lanceolate with a point, crenate; but in the garden ſerrate. Corymbs copious on the branches, compound, ſubſeſſile, or elevated on the leafy branchlets, on divaricating peduncles. Flowers white, ſcarcely larger than thoſe of Elder. Calyx ſpreading very much, acutely five-toothed. Petals oval, concave. Stamens about twenty-four. Germ depreſſed, villoſe. Styles ſhorter than the corolla and ſtamens. Berry globular, fulvous, the ſize of a pea, umbilicated with the calyx; pulpy, five-ſeeded [a]. The fruit, according to Scopoli, is as large as the common Medlar; the ſeeds ſubovate and compreſſed.

Native of the South of Europe, common on Caucaſus, and in the Cherſoneſus Taurica; alſo in China. It flowers with us in may. Cultivated in 1620, as appears from Parkinſon [b].

It has the names Pyracantha in Latin, and Buiſſon ardent in French from the redneſs of its berries.

2. The Medlar is a ſmall or middle-ſized branching tree. Branches woolly, armed in a wild ſtate with ſtiff ſpines, covered with an aſh-coloured bark. Leaves oval-lanceolate, ſerrate towards the point, ſomewhat woolly, on very ſhort channelled petioles. Bracteæ linear, as long as the corolla. Calyxes terminating, fleſhy, woolly within; teeth longer than the corolla. Petals white, blunt, entire, with a very ſhort claw. Stamens unequal, thirty or more, with cloven anthers [c]. Fruit an inferior turbinated berry, umbilicated at top with a wide depreſſed area, and crowned with the five linear calycine leaflets, fleſhy, reddiſh brown: pulp thick mixed with calloſe granules. It contains five gibbous, wrinkled, one-celled ſtones, in each of which are two ſeeds, but one is uſually abortive, the other is obovate, compreſſed like a lens, much pointed downwards, whitiſh with a brown ſpot at the top [d].

α. The wild tree differs from the cultivated one in having more ſlender, ſtrigoſe, thorny branches, and much ſmaller leaves, flowers and fruits. Pallas remarks, that all the parts are very ſmall in his ſpecimens from Perſia, with narrower leaves, ſerrulate frequently almoſt to the bafe. In thoſe from Caucaſus the leaves were ſomewhat larger, and ſometimes quite entire. In the Perſian Medlar, according to Gmelin, the leaves are red when they burſt from the buds. Spines only three or four lines in length, ſtout, very ſharp, ſpreading. Styles four or five. Fruit much ſmaller than in the gardens, containing five ſeeds.

Native of the South of Europe, and in Aſia. Said to grow in all the hedges about Montpellier, but ſcarcely to be reputed indigenous of Britain. It flowers in june and july.]

Mr. Miller makes two ſpecies of the Wild and Dutch Medlar. The firſt, he ſays, grows naturally in Sicily, where it becomes a large tree. It riſes with a ſtraighter ſtem, and the branches grow more upright than thoſe of the Dutch Medlar. The leaves are narrower and not ſerrate. The flowers are ſmaller; and the fruit is ſhaped like a Pear.

β. The Dutch Medlar never riſes with an upright trunk, but ſends out crooked deformed branches at a ſmall height from the ground. The leaves are very large, entire, and downy on their under ſide. The flowers are very large, as is alſo the fruit, which is rounder, and approaches nearer to the ſhape of an Apple. This, bearing the largeſt fruit, is now generally cultivated: but there is one with ſmaller fruit, called the Nottingham Medlar, of a much quicker and more poignant taſte. [There are other varieties of the fruit, which are now little noticed.

[a] Pallas. [b] Hort. kew. [c] Linn. Wilder. Knocker. [d] Gaertner.

3. This ſeldom riſes more than five or ſix feet high in Virginia, where it grows naturally in moiſt woods. Three or four feet is the greateſt height it attains in England. Branches few, ſlender, upright. Leaves alternate, pale green above, aſh-coloured underneath. The flowers are produced in ſmall bunches, on long peduncles, at the ſides and extremities of the branches. Petals dull white, with ſeveral brown ſpots on their upper ſide. Fruit ſmall, roundiſh, a little compreſſed, purple when ripe. It flowers in may, and the fruit ripens in october [a].

Petals and calycine ſegments ſometimes ſix, ſeven or eight [b].

It varies with red, black and white fruit; and was cultivated in 1700 by the Earl of Clarendon [c].]

4. This riſes with many ſlender ſtems three or four feet high, putting out ſmall ſide branches, covered with a dark purple bark. Leaves three quarters of an inch long, and half an inch broad, ſlightly ſerrate. The ſmall ſide branches which ſuſtain the flowers are very hairy and woolly, as are alſo the footſtalks and under ſide of the leaves, but their upper ſides are ſmooth and green. The flowers come out in bunches at the end of the ſhoots. The petals are long and narrow; and the ſtamens about ten in number. Fruit ſmall, black when ripe.

[Linnæus remarks, that whilſt it is young the branches, petioles, peduncles and under ſurface of the leaves are tomentoſe, but that when it is ſo far advanced as to bear fruit, it puts off the pubeſcence and becomes ſmooth. It is very nearly allied to M. canadenſis and Chamæmeſpilus. Pollich obſerves that the berries have eight, nine or ten ſeeds in them. Cluſius remarked ten, and ſometimes more; and Villars has reckoned as far as eleven.

The wood of this ſhrub is very hard, and the bark is black. The flowers are white, larger than in any of the others. The fruit is good to eat [d]; ſweet and reputed wholeſome. It has the name Amelanchier in Provence from *Amelanches*, on account of the berries having the taſte of honey.

Native of the South of Europe. It was cultivated in England in 1730 [e].]

5. This has a ſmooth ſtalk, about four or five feet high, ſending out ſlender branches covered with a purpliſh bark. Leaves about two inches long, and one inch and a half broad, yelloviſh green on both ſides, on long ſlender foot-ſtalks. Flowers axillary, four or five together in a cloſe head, purpliſh; with long, narrow, purpliſh bractes. Fruit, ſmall red.

[This ſhrub, whilſt young, is woolly, like the preceding and following ſpecies, when farther advanced it is naked. According to Crantz, the very young leaves are quite ſmooth, they gradually acquire pubeſcence, and caſt it off as they grow old: they are obovate, like thoſe of the Plum ſharply ſerrate, the ſerratures bent in towards the tip and very ſlender. Stipules linear, longer than the petioles, deciduous. Corymb from the axils pedunculed, conglobated into a head, on a ſubvilloſe peduncle, ſhorter by half than the leaves. Bractes between the flowers, linear, longer than the flower, coloured, deciduous. Teeth of the calyx ſhorter than the tube; whereas in Amelanchier they are longer. Haller, Jacquin and Scopoli affirm that the flowers have only two ſtyles [f].

Native of the Pyrenees, the mountains of Auſtria, &c. Ray found it on the higher parts of Jura, near Geneva. It was cultivated in Britain in 1683, by Mr. James Sutherland [g].]

6. This is a low ſhrub, ſeldom more than five feet high, dividing into ſeveral ſmooth branches, covered with a purpliſh bark. The leaves grow upon long ſlender foot-ſtalks; are an inch and half long, and an inch broad, ſmooth on both ſides, and ſerrate. The flowers come out in ſmall bunches at the ends of the branches; they are about the ſize of thoſe of the common Hawthorn, and are ſucceeded by ſmall fruit of a purpliſh colour.

[Native of Canada and Virginia. Cultivated in 1746, by Archibald Duke of Argyle. It flowers in april and may [h].

7. This is a large lofty tree. Branches thick, knobbed, with ſimilar tomentoſe branchlets. Leaves alternate, ſubpetioled, blunt, attenuated below, entire except towards the tip, where they are ſerrate; erect, recurved at the tip, marked with parallel nerves, the upper ſurface bright green, ſmooth, the under cinereous-tomentoſe, with the middle nerve thick; they are a ſpan long, the younger ones leſs. Petiole thick, tomentoſe. Flowers in ſpikes at the ends of the ſhoots. Spike compound, tomentoſe. Peduncles and pedicels thick, ſhort, tomentoſe, ſcaly. Scales or bractes ovate, blunt, concave, preſſed cloſe, tomentoſe. Calyx bell-ſhaped, thick, tomentoſe; ſegments blunt, erect. Filaments twenty, longer than the calyx. Anthers round. Germ hirſute. Styles the length of the calyx. Berry ovate, the ſize of a Cherry, ſubtomentoſe, yellow, pulpy. Seeds from one to five, ſemiglobular, ſmooth, larger than peas, brown: when there is only a ſingle ſeed it is globular. The fruit ſeems rather to be a pome, with from one to five cells; and the taſte of it approaches to that of the Apple: it is ripe in may and june. It flowers in october and november. Native of Japan [i].

8. This is a low ſpreading ſhrub, nor more than four or five feet high, covered with a ſmooth aſh-coloured or purple bark, when young pubeſcent, but becoming ſmooth with age. Leaves alternate, the upper ſurface bright green and ſmooth, the lower white-tomentoſe, finely netted, they are about an inch long, and three quarters of an inch broad. Petioles two lines in length, channelled above. There are two lanceolate, acuminate, deciduous, reddiſh ſtipules at the baſe of the petioles. Peduncles either ſolitary and unbranched from the tops of the twigs, or forming little corymbs of three or four flowers, which are pedunculed, ſomewhat nodding, round and pubeſcent, with a ſmall bracte at the baſe. Calyx lanuginoſe. Petals ſcarcely larger than the calyx, white tinged with purple. Stamens about nineteen. Germ inferior, roundiſh, ſmooth, reddiſh. Styles three, ſometimes four and even five. Stigmas capitate, ſulphur-coloured. Berry bright red, pear-ſhaped, or globular-ovate, flatted at top, crowned with the five-toothed calyx, the ſegments converging when the fruit is ripe; the pulp is yellow. Seeds three, ſeldom four or five, ovate, yelloviſh, ſharpiſh, convex and ſomewhat rugged on one ſide, triangular on the other [k].

Pallas deſcribes it as being ſeldom higher than a man, but in rocky ſituations not more than an ell in height: the trunk not more than an inch in diameter, with a brown cinereous bark, and a very hard, tough, compact wood: the twigs have a ſmooth teſtaceous or reddiſh bark. The corymbs commonly four-flowered, but frequently from five to ſeven-flowered, and ſometimes having three, two, and even one flower, with a leaf or two at the baſe, and an awl-ſhaped deciduous little bracte to each pedicel. Flower the ſize of Hawthorn. Calyx bluntly five-toothed. Corolla white or reddiſh white. Filaments fifteen to twenty, with ovate whitiſh anthers. Styles two, three or four, the length of the ſtamens. Berry globular, ſubumbilicate, green, next orange, then red, and finally black, ſmooth, fleſhy, inſipid, or ſlightly auſtere. Seeds two, three, or more frequently four.

Native of many parts of Europe and Siberia. Ray obſerved it on the hills bordering on the Rhine, on mount Saleve and Jura. It was cultivated in 1656, by Mr. John Tradeſcant, junior. It flowers in april and may [l].]

9. This has a ſmooth ſtalk about eight feet high, dividing into many ſmooth branches. Leaves two inches and a half long, of a thick ſubſtance, dark green on their upper ſide, but downy on their under, ſtanding upon ſhort foot-ſtalks. The flowers come out of the ſide of the ſtalk upon ſhort ſmall branches, five or ſix growing upon each in a cloſe bunch: the petals are of a purple colour, little longer than the

[a] Mill. fig. [b] Du Roi. [c] Hort. kew. [d] Villars. [e] Hort. kew. [f] Linn. [g] Hort. kew. [h] Hort. kew. [i] Thunberg. [k] Pallich. [l] Hort. kew.

calyx, which is woolly, with blunt segments. The fruit is large, roundish, and of a fine red colour when ripe.

[Cultivated in 1759, by Mr. Miller. It flowers in april and may[1].]

PROPAGATION AND CULTURE.

All these sorts are hardy enough to thrive in the open air in England, and some of them are very ornamental plants for gardens, where, during the season of their flowering, they will make a fine appearance; and again, in autumn, when their fruit are ripe, they will afford an agreeable variety, and their fruit will be food for the deer and birds; if clumps of each sort are planted in different parts of the garden, nothing can be more ornamental.

The American kinds are usually propagated in the nurseries, by grafting or budding them upon the common White Thorn, but the plants so propagated will never grow to half the size of those which are propagated by seeds; so that those plants should always be chosen which have not been grafted or budded, but are upon their own roots.

But there are many who object to raising the plants from seeds, on account of their seeds not growing the first year, as also from the tediousness of the plant's growth after; but where a person can furnish himself with the fruit in autumn, and take out their seeds soon after they are ripe, putting them into the ground immediately, the plants will come up the following spring; if they are kept clean from weeds, and in very dry weather supplied with water, they will make good progress; but if they are planted in the places where they are to remain, after two years growth from seeds, they will succeed much better than when the plants are of greater age; the ground should be well trenched, and cleansed from the roots of all bad weeds. The best time to transplant them is in autumn, when their leaves fall off; they should be constantly kept clean from weeds, and if the ground between the plants is dug every winter, it will greatly encourage the growth of the plants, so that if they are cleaned three or four times in the summer, it will be sufficient.

All the sorts of Mespilus and Crataegus will take, by budding or grafting upon each other; they will also take upon the Quince, or Pear stocks, and both these will take upon the Medlars; so that these have great affinity with each other.

MESPILUS. See *Crataegus* and *Ehretia*.

[MESSERSCHMIDIA. (*So named by Linnæus from Daniel Gottlieb Messerschmid, who travelled into Siberia.*)

Lin. gen. Reich. n. 204. *Schreb.* 252. *Gærtn. t.* 109. *Juss.* 129.

Arguzia montana. *Amm. ruth.* 38.

Stem herbaceous, leaves sessile, corollas funnel-shaped.

DESCRIPTION, &c.

1. This is a tall, rugged, rough-haired, branching shrub, with the branches panicled at the top. Leaves alternate, on long petioles, lanceolate, entire, veined, rough-haired. Spikes compound, directed one way, dichotomous, at the ends of the twigs on the top of the stem. Calyx very short. Corolla small, globular, inflated towards the border, which is small and flat. Berry depressed, rounded, surrounded by four teeth prominent in a circle, longitudinally two-parted. It has the corolla of Tournefortia with the fruit of Messerschmidia. It differs from the next species, which it otherwise much resembles, in its shrubby stem, petioled leaves, shorter calyx, and smaller salver-shaped corollas with a flat border[1].

Native of the Canary islands, where it was found by Masson. Introduced in 1779. It flowers from june to october[2].

2. Root creeping. Stem upright, a span high. Branches alternate. Leaves alternate, ovate-oblong, veined, tomentose, hoary. Corymbs or bunches of flowers often two. Calyx shorter than the tube of the corolla. Corolla white, larger than in the preceding, with the throat naked and pervious, the border plaited, and the sides membranaceous[3]. Berry juiceless, globular, umbilicate, obscurely striated, brown-ash-coloured, having two stones in it, bipartile: rind thick, fungous-coriaceous: stones roundish, convex on one side and longitudinally striated, flattish on the other, three-celled; the two lateral cells having seeds, the middle one barren, half open at top. Seeds four, oblong, slightly attenuated upwards, so obscurely angular as to be in a manner round[4].

Native of Siberia. Introduced in 1780, by Peter Simon Pallas, M. D.[5]

DESCRIPTION, &c.

This is a tree with opposite lanceolate leaves, five times as long as the internodes, quite entire, the upper surface smooth and green, the under glaucous and smooth; on very short petioles. Flower in each axil of the leaves sessile. Petals very large, rounded.

[1] Linn. suppl. [2] Hort. kew. [3] Linn. mant. and suppl. [4] Gærtner. [5] Hort. Kew.

Germ within the calyx. Style thick, the length of the ſtamens. Stigma capitate.

Native of the Eaſt Indies. Rheede ſays, it is much cultivated in Malabar, for the beauty of the flowers, which come out there in July and auguſt; and that it bears fruit in ſix years from the nut, continuing frequently to bear during three centuries.

He deſcribes it as a very large tree, ſpreading like the Lime, with flowers the ſize and ſhape of the wild Roſe or Sweet Briar, but with only four white petals. Fruit, when it begins to ripen ſmooth and greeniſh, but rufous and wrinkled when ripe, with a rind like that of the Cheſtnut, and three or four kernels within, the ſhape and ſize, ſubſtance and taſte of Cheſtnuts.

COR. *Petals* five, concave, nearly ſeſſile, deciduous.

STAM. very long, ſtanding out, free or ſeparate. *Anthers* incumbent.

PIST. *Germ* turbinate, flattened to the bottom of the calyx. *Style* filiform, erect. *Stigma* ſimple, ſmall, ſcarcely dilated.

PER. *Capſule* three-celled (ſometimes four-celled), three-valved (ſometimes four-valved), partly covered with the belly of the calyx.

SEEDS very numerous (when unripe) linear-chaffy; when ripe, very few, rounded or angular.

ESSENTIAL CHARACTER.

Cal. five-cleft, half-ſuperior. *Pet.* five. *Stam.* very long, ſtanding out. *Stigma* ſimple. *Capſ.* three-celled.

SPECIES.

1. Metroſideros hiſpida.
Smith in Linn. tranſ. 3. 267.
Leaves oppoſite cordate at the baſe embracing, branchlets peduncles and calyxes hiſpid.

2. Metroſideros floribunda.
Smith in Linn. tranſ. 3. 267.
Leaves oppoſite petioled ovate-lanceolate, panicle brachiate, pedicels umbelled.

3. Metroſideros coſtata.
Smith in Linn. tranſ. 3. 267. *Gærtn. fruct.* t. 171.
Leaves oppoſite petioled linear-lanceolate acuminate obſcure, panicle brachiate-decompound, pedicels ſubumbelled.

4. Metroſideros diffuſa.
Smith in Linn. tranſ. 3. 268.
Melaleuca diffuſa. *Forſt. prodr.* 37.
M. lucida. *Linn. ſuppl.* 342.
Leaves oppoſite ovate veined ſmooth on both ſides, panicles axillary or terminating, pedicels oppoſite.

5. Metroſideros villoſa.
Smith in Linn. tranſ. 3. 268.
M. ſpectabilis. *Gærtn. fruct.* t. 172.?
Melaleuca villoſa. *Linn. ſuppl.* 342.
M. ereſtuoſa. *Forſt. prodr.* 38.
Leptoſpermum collinum. *Forſt. gen. n.* 2.
Leaves oppoſite ovate veined pubeſcent underneath, thyrſes axillary or terminating oppoſite villoſe, flowers ſeſſile cluſtered.

6. Metroſideros florida.
Smith in Linn. tranſ. 3. 269.
Melaleuca florida. *Forſt. prodr.* 37.
Leptoſpermum ſcandens. *Forſt. gen. n.* 1.
Leaves oppoſite obovate-oblong veined ſmooth, thyrſe terminating, calyxes turbinate naked.

[a] Linn. zeyl.

7. Metroſideros glomulifera.
Smith in Linn. tranſ. 3. 269.
Leaves oppoſite ovate netted-veined pubeſcent underneath, heads lateral peduncled, both they and the braëtes tomentoſe.

8. Metroſideros anguſtifolia.
Smith in Linn. tranſ. 3. 270.
Myrtus anguſtifolia. *Linn. mant.* 74.
Leaves oppoſite linear-lanceolate naked, peduncles axillary umbelled, braëtes lanceolate ſmooth deciduous.

9. Metroſideros ciliata.
Smith in Linn. tranſ. 3. 271.
Melaleuca ciliata. *Forſt. prodr.* 38.
Leptoſpermum ciliatum. *Forſt. gen. n.* 3.
Leaves ſcattered almoſt oppoſite elliptic blunt coriaceous ſubciliate at the baſe, corymbs terminating hairy.

10. Metroſideros linearis.
Smith in Linn. tranſ. 3. 271.
Melaleuca linearis. *Schrader ſert. hannoveran.* 19. *t.* 11.
Leaves ſcattered linear channelled acute becoming rigid, flowers lateral cluſtered ſeſſile.

11. Metroſideros lanceolata.
Smith in Linn. tranſ. 3. 272.
M. citrina. *Curt. magaz. t.* 260.
Leaves alternate lanceolate mucronate, flowers lateral cluſtered ſeſſile pubeſcent.

12. Metroſideros ſaligna.
Smith in Linn. tranſ. 3. 272.
Leaves alternate lanceolate attenuated to both ends mucronate, flowers lateral cluſtered ſeſſile ſmooth.

13. Metroſideros capitata.
Smith in Linn. tranſ. 3. 273.
Leaves ſcattered obovate mucronulate, heads terminating, calyxes and braëtlets hairy.

DESCRIPTIONS, &c.

1. This is a very magnificent ſpecies, eaſily diſtinguiſhed by its broad ſeſſile leaves, and hiſpid branches. Flowers yellow, with wide-ſpreading ſtamens, growing in umbels, many of which unite to form a large terminating corymb, rough with red-brown hairs, like thoſe of *Robinia hiſpida*. Young plants are to be ſeen in moſt collections about London; but it has not yet flowered.

2. Flowers ſmaller, appearing to be white. Panicles formed of ſeveral branches croſſing each other, and terminating in little umbels. Sometimes the flower-ſtalks are hiſpid, ſometimes ſmooth.

3. This may be known from the preceding by its narrower, longer, more rigid and ſhining, oblique or falcated leaves. The panicle is more irregularly and repeatedly branched; its utmoſt ramifications but imperfectly umbellate. The flowers are much larger, yelloviſh white [b]. Calyx ovate-globular, with from five to twelve ribs, very ſhortly five-toothed, ſuberous, thick, aromatic. Seed, when ripe, roundiſh plano-convex, with a ſhort creſt at the top and on the back, dun-coloured, ſmooth [c].

Theſe three ſpecies were found at Port Jackſon in New South Wales, by Mr. White [d].

4. Leaves three-nerved on the lower ſurface, the nerves vaniſhing before they come to the tip. Flowers yellow [e].

It was gathered in New Zealand by Meſſrs. Forſter, and communicated to Linnæus by Dr. Sparrman.

The ſtem is much branched. Young branches and backs of the younger leaves downy; flower-ſtalks, braëtes and calyx very much ſo. Flowers red, very ornamental, ſtanding at the end of each branch in a pair of ſmall denſe panicles or thyrſes, which are truly axillary and oppoſite, though the branch, terminating abruptly, is not protruded beyond them [f].

It reſembles the preceding very much, but that is quite ſmooth and has yellow flowers: this has the ſtem, petioles, panicle, peduncles and calyx white with down, the flowers red, and the ſtamens much longer [g].—It is a native of Otaheite.

6. The branches are long, each terminated by a thyrſe of large yelloviſh flowers, with the calyx re-

[b] Smith. [c] Gærtner. [d] Smith. [e] Linn. ſuppl. [f] Smith. [g] Linn. ſuppl.

markably

markably lengthened out, almoſt as in the Clove. Leaves ſmooth. Flower-ſtalks and calyx ſcarce perceptibly ſilky, with cloſe-preſſed hairs.—Native of New Zealand.

7. This is a tree, with round oppoſite branches. Leaves on ſhortiſh downy foot-ſtalks, entire, a little waved. Flowers greeniſh yellow, cluſtered in little globular heads, which ſtand on ſimple downy foot-ſtalks about an inch long, growing laterally, moſtly oppoſite to each other, juſt above the inſertion of the uppermoſt leaf-ſtalks, and contrary to them. Each head of flowers is accompanied by a pair of oblong downy bractes; the calyx is alſo downy.

This ſpecies is but ſlightly aromatic. Gathered near Port Jackſon by Mr. David Burton.

8. Linnæus firſt took this to be a Myrtus, and afterwards determined it to be a Leptoſpermum; but the ſtamens being diſtinct, thrice as long as the petals, and twice as long as the ſtyle, which has a perfectly ſimple ſtigma, and the calycine teeth being deciduous, it is a true Metroſideros.

The ripe capſules preciſely reſemble thoſe in Gærtner's figure of Melaleuca ſuaveolens, but that is, in other reſpects, a very different plant.

Burman's ſynonym, quoted by Linnæus, can hardly belong to this plant, unleſs his deſcription is very bad; for he calls the fruit a black berry, with one cell and a ſingle ſeed.

The dried leaves of this ſpecies are tinged with the ſame metallic green that is obſervable in thoſe of Metroſideros hiſpida, and ſome other New Holland plants of this order. It is a native of the Cape of Good Hope.

9. Leaves remarkably rigid, thick and concave, their margin reflexed, as in Celaſtrus lucidus, but leſs ſhining, whitiſh and reticulated with tranſverſe veins beneath, and marked with a ſtraight central nerve. The baſe of moſt of them is ciliated with long ſpreading hairs, like thoſe on the young branches, flower-ſtalks, calyx and even petals. The flowers are large, handſome, deep-red, but few together, in a terminating corymb or umbel. Fruit large, depreſſed, projecting in three lobes much above the rim of the calyx. Gathered by Meſſrs. Forſter in New South Wales.

10. Leaves very long, narrow, ſomewhat pungent, rigid and harſh. There is a variety with ſemicylindrical leaves, more rough on the back than the more common kind. The flowers ſurround the branches in a long cylindrical ſeſſile cluſter. Their petals are green, often ſlightly downy. Stamens very long, crimſon. Capſules round, depreſſed, when old crowding each other into an angular form. This has flowered at Hanover, but not here, though it is not uncommon in our collections.

11. This is a beautiful ſhrub. The corolla very nearly reſembles that of the preceding. It firſt flowered ſeveral years ago at the Marchioneſs of Rockingham's.

12. This is diſtinguiſhed from the preceding by its tapering leſs rigid leaves, ſmaller yelloviſh flowers, the calyx and petals of which are quite ſmooth in all their parts, neither downy nor fringed.

Dr. Smith ſuſpected that this might be M. viminalis of Gærtner; but the original ſpecimens of that ſpecies in Sir Joſeph Banks's herbarium are very different, having linear-lanceolate leaves not tapering at the ends, and downy flowers. The plant figured by Rumphius in t. 17. f. 2. of his ſecond volume has ſome reſemblance to this, but he deſcribes it as very aromatic, which ours is not.

13. This differs widely in appearance from all the other ſpecies. The leaves are ſcarcely one-third of an inch in length, very ſlightly veined, obſoletely crenate, or rather rough in the margin with minute points. Flower-ſtalks ſhort, forming little terminating heads. Calyx tubular, very hairy, with foliaceous permanent teeth. Petals ſmall, purple. Stamens of the ſame colour, and about thrice as long as the corolla. Germ very ſmall, in the bottom of the calyx. Style equal to the ſtamens. Stigma a little enlarged, but not capitate. The immature fruit has the rudiments of three ſmall valves. The form of the flower is much like that of Lythrum. The leaves are dotted, but ſcarcely aromatic.

This and the three preceding were found in New South Wales by Mr. White[1].

There are ſeveral other ſpecies of this genus, but they are not yet ſufficiently aſcertained. M. gummifera of Gærtner is an Eucalyptus. M. armillaris and nodoſa belong to the genus Melaleuca.]

DESCRIPTION, *&c.*

This is a handſome biennial plant, with the habit of a Campanula. Stem ſimple, paniculed when in flower, upright, herbaceous, rough-haired, green, two feet high, the thickneſs of the little finger, milky as are alſo the branches, peduncles and calyxes. Branches alternate, axillary, flowering all over, ſpreading, reclining at the end. Root-leaves petioled, cordate; the next petioled and runcinate. Stem-leaves half-embracing, lanceolate, acute, widening into ears at the baſe, irregularly gaſhed, ſerrate, nerved, wrinkled, rough-haired, rigid, waved, aſcending at the ſides, purple at the edge, four inches long, an inch and half wide. Flowers in a panicle, peduncled, bracted, hanging down, white, four inches in diameter; ſome ſlightly tinged with purple on the outſide. Peduncles alternate, one-flowered, reflex, cylindrical, purpliſh. Bracte under the peduncle, half-embracing, cordate, acute, ſerrate, rough-haired, ſpreading, and beſides this a ſmall bracte on the peduncle itſelf.

It differs from Campanula, in the number of parts only, as Chlora does from Gentiana. Michaux ſent the ſeeds from Aleppo, and Billardiere found it on Lebanon[2].

Introduced in 1787, by Monſ. L'Heritier. It flowers from June to auguſt[3].

Mr. Curtis informs us, that he ſaw a plant of this fully blown at Meſſrs. Grimwoods at Kenſington in 1792, nearly ſix feet high, branched almoſt to the

[1] Smith. [2] L'Heritier. [3] Hort. kew.

bottom,

bottom, and loaded with a profuſion of flowers, bearing ſome diſtant reſemblance to thoſe of the Paſſion flower.

The ſeeds have not ripened in this country, ſo that being a biennial plant we cannot keep it at preſent. It requires the protection of a greenhouſe.

Leaves lanceolate-ovate.

DESCRIPTIONS, *&c.*

1. This is a lofty tree, with a trunk as large as a man can compaſs, covered with a thick aſh-coloured bark. Leaves a ſpan or more in length, and four or five inches in width, contracted into an oblong narrow point, of a hard texture, flat and ſmooth, duſky green above, brighter green beneath, on petioles an inch in length. Flowers on the extreme twigs, axillary, on thick, upright peduncles an inch and half in length, and having a very fragrant ſmell. Petals narrow in three rows; in the outer row eight, three times as broad as thoſe in the middle row, which are alſo eight; towards the top they are more round and ſometimes pointed or cuſped, but leſs ſo than in the middle row: in the inner row they are ſmall, ſhort, very much cuſped towards the top, pale yellow. Fruit oblong ſpheroidal, with a thickiſh rind, firſt green, then pale whitiſh yellow, having a very ſharp taſte, and not a very pleaſant ſmell[a]. Calyx none. Corolla double. Petals fourteen; the ſix outer greater. Filaments ſurrounding the piſtil: anthers longer than the filaments. Styles, &c. as in Nymphæa. The flowers are offered as an agreeable preſent[b].

Native of the Eaſt Indies.

2. Flowers whitiſh or pale yellow, not ſmelling ſo ſweet. Leaves broader, petioled, and even when they are young covered with a ſilky pubeſcence, like thoſe of the Willow[c]. Capſules ſeveral, in a ſtrobile-ſhaped ſpike compreſſed to an edge towards the axis, but on the outſide ſwelling into a convex back, produced at top into a ſhort point continued below into the peduncle: at firſt fleſhy, but afterwards ſomewhat coriaceous, ſoft, orange-ruſt-coloured, opening on the outer ſide. Seeds one or two, ovate, turgid-lens-ſhaped, berried, red[d].

Native of the Eaſt Indies.

Claſſ. 19. 4. Syngeneſia Polygamia Neceſſaria.

Nat. order of *Compoſitæ Nucumentaceæ. Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common inferior* five-leaved: *leaflets* thin, ſmall, obſolete. *Interior* very large, five-leaved: *leaflets* looſe, diſtinct, helmet-ſhaped, compreſſed, converging longitudinally by the margin.

COR. *Compound* of ten hermaphrodites in the diſk, and five females in the circuit.

Proper of the hermaphrodite one-petalled, funnel-form; five-toothed, erect: of the female none.

STAM. in the hermaphrodites. *Filaments* five, briſtle-ſhaped, very ſhort. *Anthers* cylindric, tubular, the length of the corollet.

PIST. in the hermaphrodites. *Germ* obſolete. *Style* filiform, longer than the ſtamens. *Stigma* obſolete.

In the females. *Germ* obovate, compreſſed, within each ſcale of the common inner calyx. *Style* from the inner ſide of the germ, briſtle-ſhaped, bent in towards the hermaphrodites, the length of the calyx. *Stigma* two-parted, ſlender, acuminate.

PER. none. *Calyx* unchanged, but the inner one larger, indurated.

SEEDS of the hermaphrodites none: of the females ſolitary, obovate, included in the proper leaflet of the inner calyx. *Down* none.

REC. with ſharp very ſmall *chaffs* ſeparating the ſeeds of the females, but not the florets of the diſk.

ESSENTIAL CHARACTER.

Cal. calycled. *Ray* of the corolla none. *Female florets* wrapped up in the calycine ſcales. *Down* none. *Recept.* chaffy.

DESCRIPTIONS, *&c.*

1. This is an annual plant. The roots ſend out ſeveral trailing ſtalks, ſix or eight inches long, [divaricating, often branched, covered with a white nap, as is the whole plant. Leaves in pairs, generally oppoſite or nearly ſo, wedge-ovate, connate, plaited, three-nerved. Flowers axillary, ſeſſile, from the baſe to the very top of the ſtem] in ſmall cluſters, very ſmall, white. [Common calyx ſimple, (the inner one being called the corolla) compoſed of five or more ſcarioſe, pellucid ſegments, ſo ſmall as to be ſcarcely viſible to the naked eye. Florets hermaphrodites ſix, and females four. Corolla of the former green, with a purple five-parted border: of the latter longer, one-leafed, plaited, with the border preſſed cloſe on both ſides, gaping at the tip, where the ſtigma iſſues forth, within green and ſmooth, without tomentoſe, becoming indurated, and then muricated on the back in two rows. In the hermaphrodites anther purple, germ effete, ſtyle ſimple, ſtigma club-ſhaped: in the females,

germ sharp at the base; style longer than the corolla, arched inwards; stigma standing out, bifid, reclining on the hermaphrodite flowers. Receptacle very small, with very small chaffs. Seeds brown, ovate, closely included within the corolla[1].

Gærtner says, that he has searched in vain for the marginal chaffs that Linnæus attributes to the receptacle, and suspects that they are nothing else but the minute leaflets with which the calyx is obsoletely calycled at the base.

Native of Portugal, Spain, Italy and the Levant. It was cultivated in 1759, by Mr. Miller, and flowers from june to september[2]. In Spain it flowers in may.

2. This also is annual. The leaflets of the calyx are from seven to nine, compressed, woolly unarmed. Receptacle awl-shaped, separated into roundish tubercles, naked. Seeds obovate, bald, included within the calycine leaflets[3].

Native of Spain, France, and the Levant.]

PROPAGATION AND CULTURE.

1. This is sometimes preserved in gardens for the beauty of its silvery leaves. If the seeds be sown in autumn, or permitted to scatter, the plants will come up in the spring, and require only to be kept clean from weeds, and thinned where they are too close. When the seeds are sown in the spring, they seldom grow the first year.

[MICROTEA. (*From μικρότης, smallness, so called from the minuteness of the parts of fructification.*)

Lin. gen. Schreb. n. 1739. *p.* 797. *Swartz prodr.* 53. *descr. t.* 12.

Class. 5. 2. Pentandria Digynia.

GENERIC CHARACTER.

Cal. *Perianth* five-leaved: *leaflets* oblong, permanent.

Cor. none.

Stam. *Filaments* five, filiform, the length of the calyx, inserted into the receptacle. *Anthers* subglobular, twin.

Pist. *Germ* superior, subglobular, echinated. *Styles* two, very short, divaricating. *Stigmas* simple, acute.

Per. *Drupe* dry, coriaceous, thin, echinated.

Seed. *Nut* roundish, smooth, with a single kernel.

ESSENTIAL CHARACTER.

Cal. five-leaved, spreading. *Cor.* none. *Drupe* dry, echinated.

SPECIES.

1. Microtea debilis.

Swartz prodr. 53. *descr.* 542. *t.* 12.

Scholleria. *Act. hafn.* 2. 210.

DESCRIPTION, &c.

It is an annual, native of the island of St. Christopher's in the West Indies[4]. Also of Granada, St. Eustatia, Guadaloupe, &c. Swartz thus describes it.—Plant smooth, a foot high. Stem herbaceous, branched, diffused, almost upright, striated, smooth. Branches irregular, diverging, weak, spreading. Leaves alternate, petioled, ovate-lanceolate, acuminate, entire, nerved, veinlets, smooth, somewhat succulent, like those of Chenopodium, deep green. Peduncles terminating or lateral, opposite to the leaves, distachyous. Racemes filiform, almost upright: flowers approximating, mostly directed one way, on short pedicels, very minute, greenish white. Bractes lanceolate, bvaline at the base of the pedicels. Fruit the size of Mustard seed, having very minute cells on the surface, echinate at the edge. Nut black, shining. Or it may be considered as a seed covered with a coriaceous echinate or muricate skin[5].

MIEGIA. (*J. Rud. Mieg published* Theses Medicæ Basil. 1721, 4°.—*And Achilles Mieg, published* Specimen observationum Anatomicarum atque Botanicarum, Basil. 1751, 4°. *I suppose this genus is named from one or both of them.*)

Lin. gen. Schreb. n. 1713. *p.* 786.

Remirea. *Aubl. guian.* 44. *t.* 16.

Class. 3. 1. Triandria Monogynia.

GENERIC CHARACTER.

Cal. *Glume* one-flowered, two-valved: *valves* ovate, concave, nerved: *upper* valve shorter, blunt; *lower* a little longer, sharpish.

Cor. two-valved. *Valves* ventricose, nerved: *outer* ovate, blunt, within and longer than the calycine valve; *inner* oblong, compressed at the tip, sharpish, the edges convoluted, longer than the outer, within the upper calycine valve.

Nectary one-leafed, ovate, gibbous at the back, somewhat compressed, acute, even, thick, suberous, thinner at the tip and edges, shorter than the corolla, opposite to the larger corolline glume, involving the germ.

Stam. *Filaments*: three, capillary, longer than the corolla. *Anthers* oblong, acute.

Pist. *Germ* oblong, subtriquetrous, within the nectary. *Style* simple, capillary, longer than the corolla. *Stigmas* two capillary.

Per. none.

Seed single, oblong, triquetrous-rounded, rolled up in the nectary, included within the permanent calyx and corolla.

Obs. *Aublet gives a character of his* Remirea *very different from this, which is from a dried specimen by Schreber. The nectary is singular in this plant.*

ESSENTIAL CHARACTER.

Cal. one-flowered, and *Cor.* two-valved. *Nect.* one-valved, involving the germ. *Seed* triquetrous-rounded, included within the calyx, corolla and nectary.

SPECIES.

1. Miegia maritima.

Lin. spec. ed. Willd. 311.

Remirea maritima. *Aubl. guian.* 1. 44. *t.* 16.

DESCRIPTION, &c.

Root creeping. Culms half a foot high covered with leaves branched at the top. Leaves lanceolate striated acute rigid. Panicle terminating contracted into an ovate spike.—Native of the sandy coasts of Cayenne and Guiana[6].

MIGNONETTE. See *Reseda.*

MILFOIL. See *Achillea.*

MILIUM (*of Pliny. So called of* Mille, *a thousand; because of the multitude of its grains.*)

Lin. gen. n. 79. *Reich. n* 85. *Schreb. n.* 110. *Juss.* 29. *Tournef. t.* 298.

Class. 3. 2. Triandria Digynia.

Nat. order of *Gramina, Graminee*, or *Grasses.*

GENERIC CHARACTER.

Cal. *Glume* one-flowered, two-valved: *valves* ovate, acuminate, almost equal.

Cor. two-valved, less than the calyx: *valves* ovate, one less.

Nectary two-leaved: *leaflets* ovate, obtuse, gibbous at the base.

Stam. *Filaments* three, capillary, very short. *Anthers* oblong.

Pist. *Germ* roundish. *Styles* two, capillary. *Stigmas* pencil-form.

Per. none.

Seed single, covered, roundish.

ESSENTIAL CHARACTER.

Cal. two-valved, one-flowered: valves almost equal. *Cor.* very short. *Stigmas* pencil-form.

SPECIES.

Culm branched, flowers panicled uſually in pairs hirſute.

DESCRIPTIONS, *&c.*

1. Culms a palm in height, even, very tender. Leaves narrow, with hairs ſcattered over them underneath, and the throat bearded. Panicle diſperſed on every ſide. Pedicels as ſlender as a very fine hair. Calycine valves ovate, ſomewhat ventricoſe, acuminate, equal in length. Seed the length of the calyx. Awn terminating, curved, longer than the flower.
Native of the Cape of Good Hope[a].

2. Culm from one foot to two feet in height, ſimple, upright, round, jointed, ſmooth. Leaves broadiſh, entire, ſtriated, even. Sheaths beardleſs, cloſed. Panicle upright, ſimple: branches alternate, ſcattered, upright. Florets pubeſcent, two together, one generally leſs than the other, on very ſhort pedicels, one ſhorter than the other, ſurrounded at the baſe with a duſky ring. Rachis angular, filiform, rough-haired. Calycine glumes equal, acuminate, rough-haired on the outſide. Corolline glumes ſmaller, equal, ovate, the outer more ſhortly awned. Anthers very minute, brown. Stigmas feathered black-purple. Seed oblong, ſhining.
Native of Jamaica, in moiſt meadows[b].

3. This is a very ſmall annual plant, extremely hard to aſcertain, from the difficulty of ſeeing its characters. The ſpikes are concealed by ſmall awns, through which very ſmall ſeeds may be diſtinguiſhed, of the ſame form and colour with thoſe of Panicum viride, but only one-fourth or one-fifth of the ſize[c]. Panicle linear-lanceolate, gloſſy, from an inch and half to three inches in length. Calyx bellying and colourleſs at the baſe, finely ſerrulated at the edges, the longer valve awn-pointed. Larger valve of the corolla terminating in four little teeth, the ſmaller valve in two, much ſmaller than the calyx[d]: ſcarcely perceptible indeed without a glaſs[e].
According to Dr. Stokes, in its ſtructure this graſs is an *Avena*, and totally different from *Milium effuſum*. Mr. Hudſon made it an *Alopecurus*, but it cannot properly be conſidered as of that genus, becauſe the corolla is two-valved. Linnæus and Gouan have made it an *Agroſtis*, and according to Withering, if it muſt be removed from this genus, it would beſt accord with that; but the remarkable ſwell at the baſe of the calyx, rendered ſtill more remarkable by its being thin, colourleſs and tranſparent in that part, ſeems ſufficient to eſtabliſh it in its preſent ſituation.
Native of Portugal, the South of France and England. Iſle of Sheppey, Gillingham in Norfolk, near Weymouth.

4. This is a perennial graſs, native of the Weſt Indies.

5. Native of Jamaica. Annual.

6. Native of Jamaica[f].

7. Root perennial and creeping. Culms ſlender, three or four feet high, with about four joints. Leaves from four to ſeven inches or a foot in length, ſmooth, thin and weak, very finely ſtriated their whole length, rough if drawn backward through the hand, three or four lines in breadth, terminating gradually in a fine point. Sheaths ſtriated, ſmooth, at the inner baſe of the leaf terminating in a membrane which is often jagged. Panicles from four inches in length to a ſpan, a foot or more, nearly upright, ſpreading and looſe; the branches of it very fine and crooked[g]. It appears to be much ſcattered from the various lengths of the pedicels, which grow in whorls, and give this graſs an airy, light and elegant appearance[h]. The filaments are longer than the corolla: the anthers firſt oblong, then forked at each end. Germ ſmooth. Styles turned back, feathered and white. It is diſtinguiſhed from the Panics, to which it has the greateſt natural affinity, by having a calyx of two valves only[i]. The corolla is like that of *Phalaris arundinacea*, but it has no hairs at the baſe, and is not keeled; it is juſt ſhorter than the calyx[k]. The height it uſually attains, the ſituation in which it grows, and the delicacy of its panicle, diſtinguiſh this from all our other Graſſes[l].
Native of moſt parts of Europe, in woods. It flowers in may.

8. This reſembles the preceding very much, ſo much that Haller regards it only as a variety. The culm is from two to three feet in height, ſmooth and round. Leaves flat, ſmooth, ſix or ſeven lines in breadth, from ſix inches to a foot in length, firſt, rough at the edges; ſheaths ſtriated, ſmooth. Panicle ſcattered, a foot or eighteen inches long and more, with more and cloſer flowers. Glumes of the calyx green, with ſmooth white edges; of the corolla whitiſh[m].
Native of Germany and Switzerland, in woods.

[a] Swartz. [b] Villars. [c] Withering. [d] Woodward. [e] Swartz. [f] Curtis. [g] Withering. [h] Curtis. [i] Stokes. [k] Curtis. [l] Krocker.

9. Culm

[a] Lin. mant.

9. Culm ſimple, upright, a foot high or more. Leaves lanceolate, ſtriated, rugged, entire, margined, patulous, ſcarcely a finger's length. Sheaths ciliate at the throat and along the edges. Panicle patulous, ſubovate. Peduncles and pedicels capillary, flexuoſe, with a yellow belt below the tip. Calyxes ovate, blunt, awnleſs, ſmooth, brownith-green.—Native of Japan[a].

10. This ſpecies reſembles the Reed. The root is annual. The culms a foot and half high. Panicle white, large and open. Calyx looſe, whitiſh, nerved and compreſſed. Valves of the corolla even and ſhining, one of them ending in a long awn. Seed black, naked, ſhining, ovate[a]. The culms are three or four feet high, and the root perennial, according to Villars.

Native of the South of France and Carniola. Introduced in 1771, by Monſ. Richard. It flowers in july[b].

11. For the deſcription ſee *Andropogon inſulare*. It is an annual Graſs, and a native of Jamaica. Browne affirms, that the roots and leaves pounded and applied externally, cure ſores and ulcers of all ſorts with more certainty than moſt other things uſed for that purpoſe. It is a ſtrong deterſive and agglutinant; and doubtleſs, would make an excellent ingredient in vulnerary apozems and infuſions.

β. Bobartia or Round-headed Graſs of Browne is a variety of this Milium. He only ſays that it grows very rank, and is eaſily diſtinguiſhed by its large ſolitated heads.

12. Culms leafy, compreſſed, decumbent, with pubeſcent joints. Leaves linear, narrow, quite ſmooth, as are alſo the joints. Panicles ſeveral, on long peduncles, from the upper ſheaths; each a ſpan long, ſtiff, ſimply branched. Pedicels commonly two-flowered, villoſe, thickened, with a ſuburbicular receptacle long-haired at the edge. Beneath each flower a blackiſh ring. Lower flower ſubſeſſile. The lower peduncles are frequently twice two-flowered. Calyx lanceolate, acute, one-flowered: valves equal, hairy on the outſide. Corolla almoſt cartilaginous, ſmooth, ſhining, ſhorter than the calyx: outer valve convex, with a ſtiff point at the top concealed within the calyx, and the edges ſlightly bent in; the inner awnleſs, flat, with the edges bent in and converging at the baſe. Anthers bifid at both ends. Germ minute. Styles white, almoſt the length of the corolla. Stigmas long, feathered, brown.

If the pencilled ſtigma be the eſſential character of *Milium*, this Graſs ſhould be referred to *Agroſtis*: but the habit, calyx concealing the corolla, and the ovate form of the corolla, which is not acuminate although it has a point, all forbid this arrangement.

Native of the Eaſt Indies[c].

Nat. order of *Compoſitæ Oppoſitifoliæ. Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* one-leafed, three-parted, very large, converging into a plane-three-ſided form, permanent: the two inner leaflets equal, ſubovate, acute, flat; the outer twice as large, roundiſh, acuminate, flat, cordate, more deeply divided from the reſt.

COR. *Compound* half-radiate. Corollets hermaphrodite two, within the ſmaller calycine leaflets: female one, within the large calycine leaflet.

Proper of the hermaphrodites one-petalled, tubular, erect, five-toothed—of the female ligulate, erect, blunt, concave, emarginate.

STAM. in the hermaphrodites: *Filaments* five, capillary. *Anthers* as many, erect, linear, connected by the middle of their ſides, the length of the corolla, acute.

PIST. in the hermaphrodites: *Germ* oblong, very ſlender. *Style* filiform, the length of the corollet. *Stigmas* two linear, weak, blunt, ſpreading.—In the females: *Germ* large, three-cornered. *Style* filiform, the length of the corollet. *Stigmas* two, briſtle-ſhaped, reflex, long.

PER. none. *Calyx* converging into a three-cornered figure.

SEEDS in the hermaphrodites none. In the females ſolitary, narrower towards the baſe, blunt, oblong, three-ſided. *Down* none.

REC. *Common* very ſmall, naked.

OBS. *In* M. quinqueflora *the female corollet is trifid, and there are four hermaphrodite tubular corollets. Calyx two-valved. Style of the male ſimple, of the female bifid.—The calyxes have always from ſeven to nine flowers.* Cavanilles.

ESSENTIAL CHARACTER.

Cal. three-valved. *Ray* of the corolla halved. *Down* none. *Recept.* naked.

Stem grooved, branches oppoſite decuſſated, leaves lanceolate ſerrate, flowers glomerate.

DESCRIPTIONS, *&c.*

1. Stem two feet high, ſtiff, ſmooth, grooved, brachiate. Root annual. Leaves oppoſite, triple-nerved, netted. Petioles connected at the edge, with a blunt reflex ſtipule interpoſed between them. Panicles trifid, dichotomous, with one-flowered pedicels. Calyx two-valved, ſqueezed or contracted, when paſt flowering converging into a globe. Male floret yellow; female one, three-parted. Style in the males ſimple, in the females bifid[a].]

It riſes with an herbaceous branching ſtalk from four to five or ſix feet high. Leaves about four inches long, and three inches broad towards their baſe, drawing to a point at the end, ſlightly ſerrate, having two veins on each ſide the midrib, which diverge and join to it near the baſe, meeting again at the point, which is generally oblique to the foot-ſtalk, which is about an inch long, and has the leaf running down on each ſide of it; the leaves are of a light green and hairy. The peduncles come out at the diviſions of the ſtalk; they branch out again by pairs, and terminate in looſe ſpikes of yellow flowers, compoſed of four or five male or imperfect hermaphrodite florets, which have no ſeed, and one female ligulate floret, which is ſucceeded by a ſingle, oblong, angular ſeed, wrapped in the calyx. It flowers in july and auguſt, and the ſeeds ripen in autumn.

It was diſcovered by Dr. William Houſtoun at Campeachy in the year 1731.

[a] Thunberg. [b] Linn. Villars. [c] Hort. kew. [d] Retzius.

[a] Linn. mant.

β. This

β. This approaches near to the preceding, but the ſtalks riſe ſix or ſeven feet high, branching out very wide. The leaves are ſeven inches long, and four inches and a half broad towards their baſe, ending in long acute points; they are more deeply ſerrate, and have ſeveral large black ſpots ſcattered over them; their ſurface is rougher, and they are of a darker green. The upper leaves are long and lanceolate. The pedunckles branch out wider, and the ſpikes of flowers are ſhorter. It was diſcovered by Mr. Robert Millar at Campeachy, in 1734.

2. This is alſo an annual plant, riſing with an herbaceous ſtalk upwards of two feet high, branching out at a ſmall diſtance from the root into three or four ſlender ſtalks, which are naked almoſt to the top, where they have two ovate-lanceolate leaves placed oppoſite, about two inches long, and three quarters of an inch broad near their baſe, ending in points; they are hairy, ſtand on naked foot-ſtalks near an inch long, and are rough; they have three longitudinal veins, and are ſlightly indented on their edges. The flowers come out at the foot-ſtalks of the leaves, in ſmall cluſters. The common calyx is compoſed of three orbicular leaves, compreſſed together. In each of theſe are two imperfect hermaphrodite florets, which are barren, and one female ligulate fruitful floret, to which ſucceeds a roundiſh angular ſeed, incloſed in the calyx. It was diſcovered at Campeachy by Dr. Houſtoun.

[According to Gærtner, the calyx of this is ſingle and three-valved; one of the valves is very large, ſubcordate, crenulate, with an oval cavity in the middle; the two other valves are much ſmaller, lanceolate-ovate, almoſt equal, cloſing the cavity of the larger valve in front. There is no veſtige of chaffs in the receptacle. Seed oblong, acuminate downwards, ſubtriquetrous, reddiſh cheſtnut-coloured, ſmooth, bald.—The preceding has a double calyx, the former one-leafed, unequally trifid, the latter augmented with five unequally leaflets, lying on the inner ſurface of the former: both are permanent, forming an involucre to the ſeed. The inner leaflets of the calyx may be regarded as chaffs, ſince they correſpond with the number and different ſizes of the germs; but ſince in the firſt ſpecies they are placed on the outſide of the receptacle, and the ſecond has them not, it ſeems better to refer them to the calyx. The outer ſegments of the calyx, being cloſely joined when ripe, form an ovate-turbinate, gibbous, coriaceous, black conceptacle, which incloſes the ſeed, and at the ſame time conceals the five interior leaflets, which are membranaceous, very ſlender, oblong, unequal, and reſembling chaffs. Seed ſubclavate, ſtriated, curved inwards, brown, bald.]

β. Stem upright, three or four feet high, with ovate-lanceolate leaves the whole length, near four inches long, and almoſt two broad near the baſe; they have three longitudinal veins, and towards the top there are two more which diverge from the midrib, but join again at the point; the upper ſide is of a dark green and ſmooth, the under ſide pale green, the edges are indented. Flowers axillary in ſmall cluſters, having three imperfect hermaphrodite florets and one female floret in each, on ſhort pedunckles. The calyxes are much ſmaller than thoſe of the preceding. It flowers and ſeeds here much later than the others. It was diſcovered by Mr. Robert Millar at Campeachy. [I have placed this as a variety of the ſecond, but I am not able to aſcertain whether it is ſo or not. The number of florets alone in this genus is not ſufficient to conſtitute ſpecific differences.

3. Stem red, grooved, three feet high. Branches ſomewhat ſpreading and villoſe. Leaves oppoſite, embracing, acutely ſerrate, ſmooth, three-nerved, nerves protuberant on the lower ſurface, which is glaucous. Flowers terminating, glomerate in corymbs. Common calyx deeply three-parted: the parts ovate, concave, and frequently two bractes at the baſe. Corolla yellow, villoſe at bottom: imperfect hermaphrodite florets two to five, female one. In the latter, the germ is larger, oblong-ovate, ſtriated, compreſſed. Seeds very ſmooth, longitudinally grooved, oblong-ovate.

It is an annual plant, native of Huanuco in Peru: and flowers at Madrid from ſeptember to december.

Juſſieu, deceived by dry ſpecimens, made a diſtinct genus of this plant, under the name of *Flaveria*; but in the living plant the *ligula* of the female floret is apparent.

The calyx is ſometimes two-leaved and two-flowered, and then one is male or imperfect hermaphrodite, and one female. Sometimes it is four-parted and many-flowered, having five male, and one female floret. Now and then there is only a ſingle floret, which is owing to the abortion of the reſt.

Neither is the calyx very large, nor is it always three-parted. The male florets alſo exceed two, and in the firſt ſpecies are commonly ſeven or nine. The generic characters therefore of *Milleria* ſhould be corrected thus:

Calyx ſimple, many-flowered, two-parted or three-parted.
Corolla of the hermaphrodite tubular, with a five-parted border—of the female, ligulate, emarginate or trifid.
Seed ſtriated, ſolitary in the male, none in the others.
Down none*.]

PROPAGATION AND CULTURE.

Sow the ſeeds early in the ſpring, on a moderate hot-bed. When the plants are about two inches high, tranſplant each into a ſeparate pot filled with light rich earth. Plunge them into a moderate hot-bed of tanner's bark. Shade them until they have taken root; and water them frequently. Then raiſe the glaſſes every day to give them a large ſhare of free air, when the weather is warm, and continue to water them duly, for they are very thirſty plants. In a month they will riſe to a conſiderable height, and ſhould then be ſhifted into larger pots, and plunged into the bark-bed, where they may have room to grow, eſpecially the firſt ſort. In the middle of july they will begin to flower, and the ſeeds will be ripe in a month or ſix weeks after. Gather them when they begin to change of a dark brown colour, for they ſoon fall off.

Theſe plants will continue flowering till michaelmas, or later, if the ſeaſon prove favourable: but when the cold of autumn comes on, they ſoon decay.

Species from Mr. Miller.

73. Mimoſa lutea. *Yellow Mimoſa.*
Mill. dict. n. 17.
Acacia ſpinoſa, foliorum pinnis tenuiſſimis glabris, floribus globoſis luteis, ſpinis longiſſimis. *Houſt. Mſs.*

Prickly, leaves bipinnate ſmooth, flowers globular pedunculed, prickles very long.

74. Mimoſa anguſtiſſima. *Narrow-leaved Mimoſa.*
Mill. dict. n. 19.
Acacia non ſpinoſa, floribus globoſis albis, foliorum pinnis tenuiſſimis glabris, ſiliquis ad ſingula grana tumidis. *Houſt. Mſs.*

Unarmed, leaves bipinnate, pinna very narrow ſmooth, legumes ſwelling.

75. Mimoſa campechiana. *Stag-horned Mimoſa.*
Mill. dict. n. 20.
Acacia ſpinoſa tenuifolia, ſpinis ſingulis cornu bovinum per longitudinem ſiſſum referentibus. *Houſt. cat. Mill. fig.* 4. *t.* 6.

Thorny, leaves bipinnate, pinnas narrow, with ſpines like an ox's horn ſplit longitudinally.

Species from the Plants of Coromandel.

76. Mimoſa dulcis. *Sweet-taſted Mimoſa.*
Roxb. corom. 67. *t.* 99.

Thorns ſtipular, leaves bigeminate, leaflets obliquely oblong, ſmooth, pointed.

77. Mimoſa Xylocarpa. *Wood-fruited Mimoſa.*
Roxb. corom. 68. *t.* 100.

Leaves ſcattered in pairs, pinnate, leaflets from two to four-paired, entire, oblong, ſmooth, the outer pair largeſt, glands on the petioles, ſtipules lanceolate.

Species from the Linnean Tranſactions, &c.

78. Mimoſa myrtifolia. *Myrtle-leaved Mimoſa.*
Smith in Linn. tranſ. 1. 252. *New. Holl.* 51. *t.* 15. *Cart. magaz.* 302.

Leaves elliptic lanceolate oblique quite entire cartilaginous at the edge, heads in axillary racemes, legumes linear with a thick edge.

79. Mimoſa ſuaveolens. *Sweet-ſcented Mimoſa.*
Smith in Linn. tranſ. 1. 252.

Leaves linear acuminate ſtraight cartilaginous at the edge, the primordial ones pinnate, branches triquetrous.

80. Mimoſa hiſpidula. *Little hairy Mimoſa.*
Smith New. Holl. 53. *t.* 16.

Leaves elliptical, oblique, rugged on each ſide and at the margin, branchlets hiſpid-pubeſcent, heads ſolitary.

81. Mimosa microphylla. *Prickly red Mimosa. Abbot's Georgia* 123. *t.* 62.
M. Intsia. *Walt. carol.* 252.
Prickly all over, leaves bipinnate eight-paired, leaflets fifteen-paired, heads axillary peduncled solitary or in pairs.

Species from Vahl's second part of Symbolæ Botanicæ.

82. Mimosa mellifera. *Honied Mimosa. Vahl symb.* 2. 103.
M. unguis cati. *Forsk. descr.* 176.
Thorny, leaves bigeminate blunt, prickles recurved.

83. Mimosa nitida. *Shining Mimosa. Vahl symb.* 2. 103.
Thorny, leaves bipinnate two-paired, a gland between each, leaflets five-paired, spikes globulose peduncled.

84. Mimosa umbellata. *Umbelled Mimosa. Vahl symb.* 2. 103.
Thorny, leaves conjugate and bipinnate two-paired, flowers umbelled, legumes spiral.

85. Mimosa Arak.
Vahl symb. 2. 104. *Forsk. descr.* 176.
Spines in threes straight, leaves bipinnate three-paired, proper five-paired, a gland between the lowest pair of the partial ones.

DESCRIPTIONS, *&c.*

This genus is composed of trees, shrubs, and undershrubs; some are unarmed, and others have prickles or thorns either all over or at the base of the petioles. The leaves are chiefly pinnate or bipinnate, and the petiole is sometimes glandular. Flowers in heads or spikes, either axillary or terminating, some of them usually imperfect or abortive. Some of the species yield a gum from the bark, others a clammy juice from the pods. The leaves in general are contracted in the evening and expanded again in the morning; and some of the species, more sensible, yield to the touch, and are hence commonly called Sensitive plants. This genus, now become unwieldy from the number of known species, may perhaps be hereafter divided from the number of stamens and structure of the legume or pod [a].

1. The leaves on this plant are described as simple, linear and pungent or hard and prickly at the end, and growing in whorls six or seven together; but it has dissimilar leaves, and the primordial ones, or two or three first leaves which appear on the seedling plants are bipinnate. This disposition to produce dissimilar leaves occurs in several other species of Mimosa, lately introduced from New South Wales, of which country this is a native [b]. It was found there by Mr. David Nelson, and was introduced at Kew by Sir Joseph Banks. It flowers from march to may [c]. Mr. Curtis remarks, that it is some years in arriving at its flowering state: that he first saw it in flower, and afterwards with ripe seed-pots, at Mr. Malcolm's at Kennington.

2. This is a beautiful little tree, with a smooth ash-coloured bark, and large leaves, very flat, without any longitudinal rib, but with numerous nerves, they are quite smooth and on very short petioles. Stipules none. Spikes globular, axillary, small, on short pedunckles. Legume compressed, curved inwards, the length of the leaf, torulose. When not in flower, it has no appearance of a Mimosa [d].

Native of the island of Tanna. Introduced in 1775, by John Reinhold Forster, L. L. D.[e]

3. Native of Cayenne.

4. This is a tree from ten to fifteen or twenty feet in height. The trunk and branches without thorns. Leaves pinnate alternate. Leaflets five-paired, sessile, connected by a margined subulate common petiole, ovate-lanceolate, generally entire, nerved, veined, smooth. Glands solitary between each pair of leaves. Pedunckles terminating, many flowered. Flowers in a sort of spike, rather large. Calyx one-leafed, five-toothed. Corolla twice as large as the calyx, five-toothed, greenish-white. Filaments monadelphous, very long. Anthers minute. Germ oblong. Style filiform. Stigma blunt. Legume long, angular-compressed, curved, with the futures two-keeled.

Native of the West Indies, especially on the banks of rivers, flowering early in the spring [f].

5. Native of the island of St. Christopher's.

6. This is a tree thirty feet in height, with an elegant close head, and a straight trunk ten feet long, and a foot in diameter. The wood is whitish, and the bark is gray. Leaves two-paired or three-paired; leaflets subovate, blunt, dark green, the outer ones three or four inches long and much larger than the others. Spike simple, solitary, cloffish, two inches long, containing about forty flowers, that are whitish and have scarcely any smell. Legume coriaceous, whitish yellow, including a sweet whitish pulp, which is sucked by the natives. They call the tree and fruit in Martinico *Pois doux*.

Native of the West Indies [g].

7. This is a small tree, with spreading unarmed branches. Leaflets ovate, acuminate. Common petiole linear, proper scarcely any. Flowers white, in diffused racemes, ending in umbellets, having hermaphrodite and male flowers mixed. Segments of the corolla ovate. Filaments about one hundred, monadelphous. Legume compressed, curved, with few seeds.

Native of Ceylon and Cochinchina.

8. This is an upright shrub, four feet high, hairy, with spreading branches. Leaflets ovate, blunt, hairy on both sides, the lower ones smaller. Flowers terminating, conglobated into a large white head. Calyx five-cleft, upright. Corolla bell-shaped. Filaments twice as long as the corolla; with very small roundish anthers. Legume linear, straight, slender, many-seeded.

Native of Cochinchina, in woods [h].

9. This is a tree with alternate leaves. Petioles bifid, with two leaflets at the top of each division. Leaflets lanceolate-ovate, like bay-leaves, smooth, quite entire, acuminate. Flowers in panicles, from the axils and ends of the branches, scattered, many-stamened, monadelphous, monopetalous, with the germ on a pedicel [i].

Native of the East Indies.

10. This is a small tree from seven to ten feet in height. The trunk is branched and unarmed. Branches subdivided, commonly unarmed, ash-coloured, wrinkled. Stipules none. Petiole bifid, each part terminated by two, sometimes but rarely by four leaflets. Leaflets wedge-shaped, ovate, blunt, entire, a little oblique, nerved, smooth. Glands at the division of the petiole, and between the pinnas. Pedunckles axillary and lateral, cluftered, scattered, terminated by a head of flowers. Corolla whitish. Filaments monadelphous, three times as long as the corolla, capillary, purplish. Anthers minute, simple. Germ oblong, compressed, blood-red. Style awl-shaped. Stigma simple. Legume compressed, twisted. Seeds five or six, compressed a little, shining, black, fastened by a scarlet membrane [k].

Native of Jamaica and other islands in the West Indies. Browne calls it the *Black-head Shrub* or *large-leafed Mimosa*.] Miller says they call it *Dettor Long*, and that the seeds are frequently brought to England by that name. [It was introduced in 1690, by Mr. Bentick [l].

According to Sloane, the seeds are eaten by goats, and sometimes by the negroes. The bark is very astringent, and is used in lotions and fomentations in America.

11. Petiole bifid, each pedicel terminating in two leaflets, and besides these, two opposite leaflets at the division of the common petiole. Flowers monadelphous [m]. Corolla cylindrical, with a very small upright border. Filaments twice, thrice, and often four times as long as the corolla, with a five-cleft membrane connecting them at top, resembling an inner corolla. Legume long, compressed, acuminate, one-celled, two-

[a] Jaffieu. [b] Curtis. [c] Hort. kew. [d] Linn. suppl. [e] Hort. kew. [f] Swartz. [g] Idem. [h] Jacquin. [i] Loureiro. [k] Linn. zeyl. [l] Swartz. [m] Hort. kew. [n] Linn.

valved, the valves rolled in ſpirally after they are divided. Seeds ſeveral, ſubovate, ſhining black [a].

Native of the Weſt Indies.

12. Flowers many-ſtamened, ſeſſile [b]. The leaves are like thoſe of the Walnut; and the flowers are purple [c]. Native of South America. Cultivated in 1768, by Mr. Miller.

13. This alſo has purple flowers, and is native of South America [d]. It was cultivated in 1768, by Mr. Miller [e].

14. This is a tree with rigid branches, that are flexuoſe from bud to bud. Under each bud is a pair of horizontal, whitiſh ſtipular thorns, the length of the leaves. Leaves petioled, conjugate or one-paired, with pinnate, ſix-paired leaflets. Common petiole terminated above by a gland, beneath by a prickle. Leaflets oblong-linear, blunt, at equal diſtances, the loweſt ſmaller. Legume oval, a hand in length and half as much in breadth, compreſſed, with large ſcattered ſeeds.

Native of the Cape of Good Hope [f].]

15. This has trailing herbaceous ſtalks, putting out roots at every joint, and ſpreading to a conſiderable diſtance. In the ſtove at Chelſea, a ſingle plant, in one ſummer, ſpread near three feet ſquare, and the branches were ſo cloſely joined, as to cover the ſurface of the bed: but when they are permitted to grow thus, they ſeldom produce flowers. The leaflets are narrow, and the petioles are ſhort and ſmooth. Flowers axillary, on naked peduncles about an inch in length; they are of a pale yellowiſh colour, and are collected into ſmall globular heads. Legumes ſhort, flat, jointed, containing three or four compreſſed, roundiſh ſeeds.

[This ſpecies is ſo very ſenſible as to contract its leaves on every ſlight touch or change of the atmoſphere; a puff of breath from the mouth will make an impreſſion on it; and Sir Hans Sloane relates, that having marked his name on a bed of it with a ſtick, it continued viſible for ſome time.

Native of Jamaica in the paſtures or ſavannahs [g]. Cultivated by Mr. Miller in 1759.]

16. The leaves of this tree divide into many ramifications; the leaflets are roundiſh, and placed in a very regular order. The ſeeds, which are flat, and one half of a beautiful red colour, the other half of a deep black, grow in long twiſted pods, and hanging by a ſmall thread for ſome time out of the pod, when they are ripe, make a very agreeable appearance. It was brought from the Bahama iſlands by Mr. Cateſby, in the year 1726.

[It agrees with M. Unguis cati in its ſtipular ſpines, and long pods ſpirally convoluted, but differs entirely from it in the leaves [h].

17. This prickly ſhrub is common in moſt of the ſugar colonies, eſpecially in Antigua, where the leaves are frequently uſed, mixed with corn, for their riding horſes; and it is thought to free them from botts and worms. It grows in a ruffed form, and ſeldom riſes above five or ſix feet from the ground, though it ſpreads a great deal more in its growth [i]. Browne names it Fingrigo or thorny Mimoſa. According to Linneus it is a native of the Eaſt Indies.

18. The lower flowers of the ſpikes are ten-ſtamened and barren; the upper ten-ſtamened and fertile. Native of the Eaſt Indies [k].]

19. This riſes with a ſlender woody ſtalk ſeven or eight feet high, armed with ſhort recurved thorns. The leaves grow upon long foot-ſtalks which are prickly, each ſuſtaining two pairs of wings; the outer pair has two lobes which join at their baſe, and are rounded on the outſide, but ſtraight on the inner edges, ſhaped like a pair of ſheep-ſhears; they are much larger than the inner, are almoſt two inches long, and one inch broad in the middle. From the place where theſe are inſerted in the ſtalk, come out ſmall branches, which have one or four globular heads of pale purpliſh flowers coming out from the ſide, on ſhort peduncles; and the principal ſtalk has many of thoſe heads of flowers on the upper part for more than a foot in length; and this, as alſo the branches, is terminated by like heads of flowers. Pods broad, flat, jointed, opening by two valves; containing one, two or three compreſſed orbicular ſeeds. The leaves move but ſlowly when touched, but the foot-ſtalks fall, when they are preſſed pretty hard. [Linneus remarks, that the flowers are five-ſtamened and apetalous.

Native of Brazil. Introduced before 1733, by William Houſtoun, M. D. [l] Mr. Miller ſays, that he ſent the ſeeds from La Vera Cruz, where it grows naturally.

20. Roots compoſed of many hairy fibres, which mat cloſe together, from which come out ſeveral woody ſtalks, which decline towards the ground, unleſs they are ſupported; they are armed with ſhort recurved ſpines, and have winged or pinnate leaves, compoſed of four, and ſometimes five pinnas, whoſe baſes join at a point, where they are inſerted into the foot-ſtalk, ſpreading upwards like the fingers of a hand. Flowers from the axils, on ſhort peduncles, collected in ſmall globular heads, of a yellow colour. Pods ſhort, flat, jointed, in cloſe cluſters, almoſt covered with ſtinging hairy covers.

[Calyx funnel-form, trifid, with one lobe wider. Corolla none. Filaments four, ſix times as long as the calyx, erect, filiform. Germ roundiſh. Style awl-ſhaped, a little ſhorter than the ſtamens. Stigma acute [m]. Legume oblong, compreſſed, jointed, girt by a filiform future with harmleſs ſpinules: joints from two to four, papery, one-celled, ſeparating from each other and from the future, and opening by two valves. Seeds ſolitary, rounded, lens-ſhaped, ſmooth, ſhining, honey-coloured or rufeſcent, with an eye-like ſtreak in the middle on each ſide, and faſtened by a capillary chord to the inner margin of the valves: ſkin ſingle, papery, thin: albumen watery, pale, thin, adhering cloſe to the ſkin: embryo ſtraight, yellow: cotyledons orbicular, leafy: plumule none: radicle rather large, retracted, ſtraight, centrifugal [n].

Native of Brazil.] It is the moſt common of any ſpecies in the iſlands of the Weſt Indies, and in the Engliſh gardens. The ſeeds are ſold in the ſeed-ſhops, by the name of Humble Plant. [Parkinſon calls it Mimick, Mocking, or thorny Senſitive Plant or Shrub, and ſays that he ſaw a living plant of it in a pot at Chelſey in Sir John Davers garden, where divers ſeeds being ſown about the middle of may 1638 and 1639, ſome of them ſprang up to be near half a foot high.

Senſitive plants were not unknown to the ancients. Theophraſtus ſpeaks of the Αιγυπτιον as growing about Memphis in Egypt; and Pliny of the *Ægilynomene*, ſo called from its contracting the leaves at the approach of the hand.

It is thus characterized in the flowing poetry of Darwin:

" Weak with nice ſenſe, the chaſte Mimoſa ſtands,
" From each rude touch withdraws her timid hands;
" Oft as light clouds o'erpaſs the ſummer glade,
" Alarm'd ſhe trembles at the moving ſhade;
" And feels, alive through all her tender form,
" The whiſper'd murmurs of the gath'ring ſtorm;
" Shuts her ſweet eye-lids to approaching night,
" And hails with freſhen'd charms the riſing light."

" Naturaliſts" ſays Dr. Darwin, " have not explained the immediate cauſe of the collapſing of " the Senſitive plant; the leaves meet and cloſe in " the night during the ſleep of the plant," (which in Sweden, according to Linneus, is from ſix in the evening to three in the morning during the months of june and july) " or when expoſed to much cold in " the day time, in the ſame manner as when they are " affected by external violence, folding their upper " ſurfaces together, and in part over each other like " ſcales or tiles; ſo as to expoſe as little of the upper " ſurface as may be to the air; but do not indeed " collapſe quite ſo far: for when touched in the night " during their ſleep, they fall ſtill farther, eſpecially " when touched on the foot-ſtalks between the ſtems

[a] Jacquin. [b] Linn. [c] Plumier. [d] Idem. [e] Hort. kew. [f] Linn. mant. [g] Browne and Sloane. [h] Linn. [i] Browne [k] Linn. [l] Hort. kew. [m] Linn. [n] Gærtner.

" and

" and the leaflets, which ſeems to be their moſt ſenſi-
" tive or irritable part. Now as their ſituation after
" being expoſed to external violence reſembles their
" ſleep, but with a greater degree of collapſe, may it
" not be owing to a numbneſs or paralyſis conſequent
" to too violent irritation, like the faintings of animals
" from pain or fatigue? A Senſitive plant being kept
" in a dark room till ſome hours after day-break, its
" leaves and leaf-ſtalks were collapſed as in its moſt
" profound ſleep, and on expoſing it to the light,
" above twenty minutes paſſed before the plant was
" thoroughly awake and had quite expanded itſelf.
" During the night the upper or ſmoother ſurfaces of
" the leaves are appreſſed; this would ſeem to ſhow
" that the office of this ſurface of the leaf was to ex-
" poſe the fluids of the plant to the light as well as to
" the air[f]."]

It would be to little purpoſe to trouble the reader with the ſeveral idle ſtories related of theſe plants by travellers, nor to inſert what has been ſaid by others, who have attempted to account for the motion of the leaves of theſe plants on their being touched; I ſhall therefore only mention what I have myſelf obſerved in theſe plants, for more than forty years that I have cultivated them.

The firſt is, that they are more or leſs ſuſceptible of the touch or preſſure, according to the warmth of the air in which they grow; for thoſe plants which are kept in a warm ſtove, contract their leaves immediately on being touched, either with the hand, a ſtick, or any other thing, or by the wind blowing upon them: ſome of the ſorts only contract their ſmall leaves, which are placed along the midrib; others not only contract their ſmall leaves, but the foot-ſtalk alſo declines downward on being touched: the firſt are called Senſitive, and the ſecond Humble Plants; but when theſe plants are placed in a cooler ſituation, they do not move ſo ſoon, nor contract ſo cloſely, as thoſe which are in a greater warmth; and thoſe which are entirely expoſed to the open air, have very little motion, but remain in one ſtate, neither expanded nor cloſed, but between both, eſpecially in cool weather; nor do theſe ſhut themſelves at night, as thoſe do which are in a warm temperature of air.

The ſecond is, that it is not the light which cauſes them to expand, as ſome have affirmed, who have had no experience of theſe things; for in the longeſt days of ſummer, they are generally contracted by five or ſix in the evening, when the ſun remains above the horizon two or three hours longer; and although the glaſſes of the ſtove in which they are placed, are covered cloſe with ſhutters to exclude the light in the middle of the day, yet if the air of the ſtove is warm, the leaves of the plants will continue fully expanded, as I have ſeveral times obſerved. Nor do theſe plants continue ſhut till the ſun riſes in the morning, for I have frequently found their leaves fully expanded by the break of day in the morning; ſo that it is plain the light is not the cauſe of their expanſion, nor the want of it that of their contraction.

I have alſo obſerved, that thoſe plants which are placed in the greateſt warmth in winter, continue vigorous, and retain their faculty of contracting on being touched; but thoſe which are in a moderate warmth, have little or no motion.

When any of the upper leaves of theſe plants are touched, if they fall down and touch thoſe which are below them, it will occaſion their contracting and falling, ſo that by one touching another, they will continue falling for ſome time. When the air of the ſtove in which theſe plants ſtand, is in a proper temperature of warmth, the plants will recover themſelves, and their leaves will be fully expanded in about eight or ten minutes. I have frequently watched them as they have been recovering, and have always found it has been by a vibratory motion, like the index of a clock.

Some of the ſorts are ſo ſuſceptible of the touch, that the ſmalleſt drop of water falling on their leaves will cauſe them to contract, but others do not move without a much greater preſſure.

The roots of all the ſorts have a very ſtrong diſagreeable odour, almoſt like that of a common ſewer. I have met with ſome accounts of theſe plants, in which it is mentioned, that the leaves and branches have a poiſonous quality, and that the Indians extract a poiſon from them, which kills by ſlow degrees, and that the root of the plant is the only remedy to expel it; but how far this is true I cannot ſay, having never made any experiments on the qualities of theſe plants; but if theſe plants have ſo deadly a quality as related, this ſenſibility with which they are endued, may be deſigned by Providence to caution perſons from being too free with them, and as many of them are ſtrongly armed with thorns, that is a guard againſt their being eaten by animals; for in all the enquiries which I have made of thoſe perſons who have reſided in the countries where they naturally grow, I could never learn that any animal will browſe upon them.

Mr. Miller has another ſpecies (n. 4.) to which he gives the ſame name of *pudica*, and which was diſcovered by the late Dr. Houſtoun at La Vera Cruz. This has woody ſtalks, which decline to the ground, ſpreading out two or three feet from the root, and ſend out ſeveral ſide branches, armed with ſhort yelloviſh ſpines under the foot-ſtalks of the leaves, and cloſely covered their whole length with briſtly ſtinging hairs: the foot-ſtalks are three inches long, and at the top ſuſtain four ſingle winged leaves, whoſe baſes meet in a point, but ſpread above like the fingers of an open hand: theſe wings are about three inches long, and have ſmall narrow leaflets cloſely ſet by pairs along the midrib, which is alſo covered on the under ſide with the like briſtly hairs as the ſtalk. Flowers axillary, upon pretty long peduncles, collected into globular heads, and of a pale yelloviſh colour. Pods ſmall, jointed, containing two or three ſhining black ſeeds. The common Humble Plant has the wings of the leaves ſhorter than this, and the ſtalks are not hairy.

[22. This climbs to the tops of the talleſt trees, to the height of one hundred and fifty feet, frequently overſpreading many of the neighbouring branches, and forming large arbours. The withs are ſlender, but tough and flexile[e], ſtriated, ſtiff, and ſmooth. Common petioles long, oppoſite, thickened at the baſe, round, very ſmooth, terminating in a tendril, by which the branches are ſupported. Pinnas four-paired, petioled, oblong, blunt at top, emarginate, nerved, ſmooth on both ſides, ſhining. Glands none. Tendril long, upright, bifid at the end. Spikes axillary, erect, very long, many-flowered. Flowers approximating, ſubſeſſile, ſmall. Petals five, erect, oblong, green. Filaments twenty to twenty-four, yellow, ſhorter than the corolla, and ſpringing from its baſe. Anthers globular. Legume very large, from ſix to eight feet long, and five or ſix inches wide, compreſſed, variouſly writhed, two-valved. Seeds ſeveral, orbicular, ſomewhat compreſſed, with a hard brown ſhining rind, and a black mark. Moſt of the flowers are abortive[f].

Browne ſays that the female plants throw out their flowers ſeparate, and are ſucceeded by ſo many pods. Loureiro found no male flowers, but all hermaphrodites. He aſſigns, as Linneus does, no more than ten ſtamens to the flowers, and ſays that they are twice as long as the corolla.

Native of both Indies and Cochinchina. In the Weſt Indies it is called *Cocoon*.]

23. This was diſcovered by Dr. Houſtoun at La Vera Cruz, growing in ſtagnant water, where the ſtalks were very broad and flat, and floated on the ſurface: but where the water was dried up the ſtalks grew upright and were round, which is always the caſe when the plant is cultivated in a garden; ſo that they might eaſily paſs for different plants with thoſe who never ſaw them growing in both ſituations. When cultivated in a garden this has great reſemblance to the 27th, but the ſtalks never grow ſo erect, the wings of the leaves are longer, and ſtand more horizontal in this,

[e] Browne. [f] Swartz.

[f] Loves of the Plants, p. 25.

the heads of flowers are much larger, the ſtamens are longer, and the flowers on the under ſide of the ſpike which have no ſtamens are double; the pods alſo are ſhorter, and much broader than thoſe of punctata. It is an annual plant in this country: and has ſince been found in the iſland of Barbuda, in a marſhy ſpot.

[Stems round, herbaceous, ſmooth, procumbent, rooting at all the joints. Leaves three-paired or four-paired, contracting with the leaſt touch. From the axils of theſe ſpring erect peduncles, four or five inches high, with ſcales the whole length, ſuſtaining handſome, yellow, almoſt globular heads, the ſame ſize with thoſe of red Clover. Flowers different in ſhape, nature and uſe: thoſe in the middle truly five-petalled, in ſmall five-cleft calyxes, with many long ſtamens; but thoſe in the circuit inſtead of ſtamens have oblong, beautiful, golden leaflets, much wider and handſomer than the true petals, which are ſmall and of a greeniſh colour. Theſe double flowers are barren; but the ſingle ones are ſucceeded by flat, ſmooth, two-valved legumes, containing ſeveral, black, ſhining, compreſſed ſeeds [a].—Cultivated by Mr. Miller before 1733.

24. Stems ſlender, a foot high, ſimple, ſmooth, compreſſed at bottom, above ſtriated and three-ſided. Leaflets ſcarcely an inch long, with about twelve pairs: pinnas linear, blunt, mucronate, ſmooth, appearing in the magnifier to be ciliate-ferrate. Petioles not glandular. Stipules ſemicordate, attenuated, ſmooth. Peduncles axillary, ſolitary, ſhorter than the leaf, with two oblong leaves in the middle. Flowers in a globular head, the ſize of a pepper-corn. Legumes about ſix, unguicular, pedicelled, oblong, compreſſed, ſmooth, four-ſeeded. This is wrongly placed under the name of natans, among the ſpecies with ſimply pinnate leaves, in Syſtema Vegetabilium [b]. Obſerved by Koenig in the Eaſt Indies.

25. Stems herbaceous, angular, ſmooth, floating, putting out rooting fibres at the lower joints. Leaves petioled: pinnas ſmall, the inmoſt ſmaller than the others, linear-oblong, quite entire. Glands none. Stipules ovate-rhomboidal, blunt iſh. Peduncles axillary, ſolitary, five inches long: ſpike oblong, nodding before flowering time: the lower florets a little more remote, barren and larger. Legumes compreſſed, an inch long.

Koenig ſent this under the name of *natans*, but called that which bears this name in the Supplement of the younger Linneus *triquetra*. The former is an aquatic plant, being found floating on freſh waters in the Eaſt Indies; but the latter is by no means ſo: Vahl therefore has changed the name with propriety.

Loureiro has conſtituted a new genus out of this ſpecies under the name of Neptunia. He ſays that it is cultivated in Cochinchina for ſalads, being faſtened to ſtakes in the water, that it may not float away, as it is entirely detached from the earth.

26. Spike roundiſh, nodding. Flowers ten-ſtamened, yellow; the lower ones of the ſpike without ſtamens or petals [c].—Native of the Weſt Indies. Introduced in 1774, by Joſeph Nicholas de Jacquin, M. D. It flowers in july and auguſt [d].

27. This riſes with upright branching ſtalks ſix or ſeven feet high, becoming woody towards the root, but not perennial (at leaſt they are not ſo here in any ſituation, the plants always decaying in winter;) they are ſmooth, and the leaves are compoſed of four or five pairs of long winged lobes, which have about twenty pairs of ſmall leaves ranged along the midrib; they are ſmooth and rounded at their points, of a full green on their upper ſide, but pale on their under. Theſe ſmall leaves contract themſelves together on their being touched, but the foot-ſtalks do not decline at the ſame time, as thoſe do which are titled Humble Plants, this therefore is called the Senſitive Plant by way of diſtinction. The flowers are produced upon long foot-ſtalks, which come out from the wings of the leaves, and are diſpoſed in globular heads which nod downward; they are yellow, and all thoſe which have petals have ten ſtamina in each, but thoſe ſituated round the border have neither petals nor ſtamina; thoſe on the upper part of the ſpike are ſucceeded by pods an inch and a half long, and a quarter of an inch broad, which change to a dark brown when ripe, incloſing three or four compreſſed, ſhining, black ſeeds.

[The ſtem has callous dots irregularly diſpoſed on it. The leaves are four-paired, with a depreſſed gland between the firſt pair. Leaflets twenty-paired. Peduncles with two, alternate, half-cordate bractes. Spikes oblong. All the florets ten-ſtamened, the lower ones male and caſtrated. Corolla five-petalled [e]. Browne calls it the larger ſmooth Senſitive, and ſays that it has been introduced into Jamaica from ſome other part of the world, probably from the Continent of America.]

28. Stems ſeldom more than two feet and a half high, and ſmooth. Leaves compoſed of three or four pinnas, which are ſhorter, and the leaflets much narrower than in the 23d and 27th ſorts: the heads of flowers are ſmaller, and the pods longer and narrower. It grows naturally in all the iſlands of the Weſt Indies, where it is called the Slothful Senſitive Plant, becauſe the leaves do not contract on being touched.

[The flowers are made up of many long white filaments, forming all together a round head. Pods flat, an inch long, and a quarter of an inch broad, with a round protuberance at each ſeed [f].

29. This is a lofty tree, with an upright ſmooth trunk, covered with an aſh-coloured bark. Branches diverging, bent down, ſmooth. Partial leaves twelve-paired. Univerſal petiole round, ſtriated, ferruginous-pubeſcent: partial petioles alſo ferruginous. Glands roundiſh, concave, between the petioles. Sealelets bifid, minute, at the baſe of the partial petioles. Pinnas ſixteen or eighteen-paired, halved, ſubſeſſile, acute, entire, ſmooth. Spikes pedunculed, ſubglobular, compoſed of aggregate, ſeſſile, white flowers. Peduncles axillary, ſlender. Corolla three times as long as the calyx, with a five-toothed border of a whitiſh fleſh-colour. Filaments monadelphous, twice as long as the corolla. Legume ſubcylindric, curved, twiſted, red, four or five inches long: valve blood-red within. Seeds ſpherical, ſhining-black [g].

Branches, petioles and peduncles rough-haired. Leaves ſeven-paired, with ſeventeen-paired leaflets; the loweſt ſmaller. Above the knee of the partial leaves a two-parted ſcale. Spike ovate. Flowers in bundles, one-petalled, five-cleft, monadelphous, many-ſtamened. Stamens fleſh-coloured, very long. There is a variety which is ſmooth, with leaflets from twelve to fourteen, and twenty-ſeven pinnas [h].

In Jamaica, where it is found in moſt parts of the iſland, it is called *Maſcotah* or *Wild Tamarind Tree*; it grows to a very conſiderable ſize, and is looked upon as an excellent timber wood [i].

It is a native not only of the Weſt Indies, but alſo of Japan and China.

30. This is a tree with a ſmooth aſh-coloured bark; the branches as it were in whorls, tuberous at the baſe, nodding at the end. Leaves bipinnate; the common petiole patulous and the partial ones tuberous at the baſe. The primary petiole near the baſe ſuſtains a gland, or hemiſpherical ſhining tubercle. Above the baſe of each ſecondary petiole are alſo two other glands, which are oppoſite and horned; one of theſe is frequently wanting, and the firſt pinnule occupies its place. Pinnules oppoſite, from eight to twelve-paired, ſeldom twenty-five in number, without any odd one. Theſe leaflets are unequal-ſided, paler and ſomewhat veined on the upper ſurface, on very ſhort petioles, and terminated by a ſlender point. Stipules linear, patulous, ſoon falling. Peduncles from ſome of the ends of the young ſhoots, and having tubercles diſpoſed in a ſort of ſpiral line. From each tubercle come out two peduncles in an angle of about ſixty degrees, each ſupporting from ſixteen to twenty flowers in a ſpherical head. Flowers all perfect: one in the

[a] Houſt. reliq. [b] Vahl. [c] Linn. from Miller. [d] Horſt. kew. [e] Linn. [f] Sloane. [g] Swartz. [h] Linn. [i] Browne.

middle larger than the reſt, with a one-leafed, five-cleft calyx; a tubular, five-cleft corolla, with ovate, concave ſegments, the tube twice or near thrice as long as the calyx, ſomewhat villoſe, and when examined by a magnifier appearing to have lucid dots ſcattered over it; from the bottom of this the nectary, ſtriated, ſmooth, bearing the ſtamens on its edge, as in monadelphous flowers. In the bottom of this tube lies the germ, which is lanceolate, ſubſeſſile, green, ſmooth; the ſtyle is ſlender, long and white; the ſtigma blunt, appearing rough with very minute papillæ, when examined with a glaſs. The other flowers are ſmaller, and ſcarcely one or two of theſe produce fruit. The ſtamens are five times as long as the corolla, ſlender, ſtraight, fleſh-coloured, from twenty to twenty-eight in number. Filaments connate at the baſe into a tube. Anthers green, compoſed of two globules, in which are ſmall, pellucid, ſpherical particles. Fruit four to ſeven inches long, and an inch wide; pedicelled, flat, drawn to a point at both ends, margined, yelloviſh on the outſide, firſt greeniſh and then white within, and never opening. From both ſutures ſpring branched nerves, and the edge is ſlightly repand, ſometimes ſinuated here and there. Seeds elliptic, four lines long, of a reddiſh brown colour, moderately compreſſed, ſharp at one end and rounded at the other, marked on both ſides with one or two little excentrical pits and two raiſed lines forming an elliptical area: they are from ſeven to twelve in number, and faſtened to one ſuture by a ſlender twiſted thread, three lines in length, but they break looſe when ripe, and move about if the pod be ſhaken. This has been confounded with the preceding [1].

Native of the Levant. Introduced about 1745, by Richard Bateman, Eſq. It flowers in auguſt [2].

31. Native of Jamaica [3].

32. Leaves deſtitute of glands. Pinnas from twelve to twenty, an inch in length. Bundles of flowers pedunculed. Legume a ſpan long [4]. It is cultivated in the gardens at Cairo, where it flowers in june, and becomes a large tree; but Haſſelquiſt does not aſcertain whether it be a native of Egypt. Linnæus however and Forſkahl give it as indigenous of Upper Egypt. The Arabs call it *Lebbeck*, which Linnæus has adopted for the trivial name of the ſpecies.

33. This is a looſy tree, with villoſe ſomewhat hoary branches, and hoary petioles. Leaves large, three or four-paired, with glands towards the lower pinnas and within the upper ones. Pinnas many-paired: leaflets obliquely oblong, very ſmooth above, hoary beneath. Panicles axillary, three, elongated, large, diffuſed: the pedicels terminating in globular ſpikes. Flowers white, very fragrant. Legumes flat, coriaceous, much reſembling thoſe of M. latiſiliqua, but narrower and leſs waved [5]. Vahl remarks, that there is an oblong, ſeſſile gland near the baſe of the general petiole, and frequently two or four pedicels from the ſame point.

Native of the iſland of Ceylon.

34. This is a very elegant tree, quite ſmooth all over. Trunk round, with an even aſh-coloured bark, marked with tranſverſe ferruginous little warts. Leaves ſmooth, alternate: rib roundiſh, about a foot long, having a little above its origin an oval, ſeſſile, conſpicuous gland. Pinnas oppoſite, moſtly four on each ſide, nine-paired or thereabouts, without an odd one. Pinnules oblong, obſcurely ſickle-ſhaped, very blunt, quite entire, on very ſhort petioles, oppoſite, flat, an inch long. Peduncles three inches long, either ſolitary or a few together. Flowers numerous, ſeſſile or on very ſhort peduncles, extremely ſweet, in a handſome head, at the top of which is one flower, different from the reſt and abiding longer, which is probably the only fertile one, though all appear to be hermaphrodites. Calyx yellow. Corolla herbaceous [6].

35. This is a middle-ſized tree, with ſpreading branches. Leaves four or five-paired; the partial ones four-paired: leaflets ovate, acute, incurved, ſmoothiſh: petioles linear, ſhort, pubeſcent [7]. Flowers umbelled, many-ſtamened, with tomentoſe calyxes, according to Linnæus:—white, ſubterminating, in a panicle terminating in heads, and about twenty ſtamens, longer than the corolla, according to Loureiro.

Native of the Eaſt Indies, Cochinchina, and Brazil.

36. This alſo is a middle-ſized tree, with ſpreading branches. Leaves many-paired: leaflets commonly eight-paired: the common petiole thickened at the baſe, and propped by a recurved callous hook. The male flowers are many-ſtamened and monadelphous, with four-cleft calyxes and corollas. Panicle terminating, ending in duſtiſh cymes of white flowers. Loureiro did not ſee any hermaphrodite flowers.

Native of China, near Canton.

37. Native of the Weſt Indies [8].

38. Bractes half-cordate. Peduncles in threes. Flowers in heads. An obſolete gland on the common petiole below the partial pinnas. Germs globular, two-valved; with two, roundiſh, concave or hemiſpherical leaflets. Leaves very ſmooth [9].—Native of the Weſt Indies. Introduced in 1777, by Daniel Charles Solander, L. L. D. It flowers moſt part of the ſummer [10].

39. This plant, which becomes a tree itſelf, climbs up other trees, overtops them, and drags them down by its weight. The trunk is round, covered with a brown bark, and often nine inches in diameter. Partial leaves on each ſide commonly three or four, of which the two end ones, after they have dropped their leaflets, are changed into very ſtrong tendrils, which entwine the branches of any neighbouring tree, and adhere to it ſo cloſe, that they can ſcarcely be ſeparated. The proper leaflets are commonly ſeven on each ſide, oblong, blunt, emarginate. Particular ſpikes cloſe, two inches long, turned upwards and erect, about thirty together on the ſame common pedunculc, which is a foot long and ſtretched out horizontally. Flowers ſmall, herbaceous, about 150 on each particular ſpike, ſo that in the whole compound ſpike there are about 4500. To this multitude of flowers, many of which are male, ſcarcely ten legumes ſucceed, and theſe very ſeldom arrive at maturity.

Native of the Weſt Indies, where it is a great nuiſance to the ſugar planters by deſtroying the trees which they ſet to ſhelter their ſugar grounds [11].

40. This is an upright tree, about twenty feet in height, with branches ſtretched out horizontally. Spines awl-ſhaped, acuminate, ſtrong, ſubaxillary, five-lined. Leaves axillary, with the common petiole two inches long, and a ſmall, oblong, blunt, upright gland a little above the baſe. Partial pinnas an inch long: leaflets oblong, blunt, ſcarcely three lines in length. Spikes globular, axillary, ſolitary, turned upwards, on a pedunclc an inch in length. Flowers white, void of ſcent [12].

Native of Jamaica and other iſlands of the Weſt Indies; and about Carthagena in New Spain. Frequent in the iſland of Mango.

41. Peduncles long, bearing many ſpikes. Native of America [13].

42. This ſhrub riſes frequently to the height of fourteen or fifteen feet or more. It is not ſo prickly as the *tortuoſa*, (n. 56.) and its leaves are rather larger. It is of a ſpreading growth, and furniſhed with oblong flower-ſpikes, and very long legumes. It has been introduced into Jamaica from the continent, and thrives very luxuriantly in many parts of the low lands [14].

43. Legumes ovate-oblong, flat. Native of America [15].

44. Spikes globular, large, pedunclcd. Flowers white, apetalous, ten-ſtamened [16]. Legumes long, flat. It flowers in april, and the ſeeds are ripe in autumn. It was diſcovered by Dr. Houſtoun at La Vera Cruz, and ſent to Europe by him in 1729 [17]. But it had been cultivated before, in 1690, in the Royal garden at Hampton Court [18].

45. Branches unarmed, ſmooth, obſcurely angular at top, having a few ſmall dots ſcattered over them. Leaves twenty-four paired, the inmoſt ſmaller. Leaflets fifty-paired and more. Pinnas minute, ſmooth, veined when inſpected by the magnifier, acute. Petioles channelled

[1] Scopoli. [2] Hort. kew. [3] Swartz. [4] Linn. [5] Linn. ſuppl. [6] Jacquin. [7] Loureiro.

[8] Loureiro. [9] Swartz. [10] Linn. [11] Hort. kew. [12] Jacquin. [13] Idem. [14] Linn. [15] Browne. [16] Linn. [17] Idem. [18] Mill. fig.

channelled above, ſmooth, purpliſh at the baſe. Gland oblong, brown, towards the baſe of the petiole and between the two or three outer pairs, hollow. Stipules briſtle-ſhaped. The lower ſpikes axillary, ſimple, ſolitary, ſhorter than the leaf; the upper ones ſubracemoſe, in pairs, two inches long. Flowers alternate, approximating, numerous. Calyx ſmooth. Legume a little compreſſed, an inch long, linear-lanceolate, ſurrounded longitudinally by a membrane.

It has the appearance of M. Catechu, but differs in having no ſpines, ſhorter ſpikes, and the calyxes ſmooth not hoary.

Native of the Iſle of France[m].

46. This is very nearly allied to M. Houſtoni, but differs from it in having more frequent pinnules, and the leaflets very diſtinct, ovate at the baſe; whereas in M. Houſtoni they are confluent at the rachis, truncated at the baſe, and reſemble a pinnatifid leaf.

Native of the Eaſt Indies[n]. Introduced about 1769, by Mrs. Norman. It flowers from june to ſeptember[o].

47. Leaves hairy underneath. Inflorescence as in M. grandiflora, but the flowers ſmaller. Corollas viſcoſe, permanent. Legumes parallelogram-ſhaped, acuminate, flat except where the ſeeds are, very tomentoſe, ruſous. Seeds oblong, compreſſed, with a zone on each ſide, inſerted into both margins of one of the ſutures.

This is the true Gleditſchia inermis of Linnæus, for which Duhamel, Du Roi and others have taken an unarmed variety of Gleditſchia triacanthos[p]; which ſee in this Dictionary.

It is one of the moſt beautiful ſpecies of the genus. The petals being very large, and of a fine purple colour, with their ſtamens ſtretched out to a conſiderable diſtance beyond the petals, the flowers make a charming appearance when the trees are covered with them; and when the pods, which are ferruginous, are ripe and hanging plentifully from every bough, the view of the trees is very pleaſing from a ſmall diſtance. The ſeeds were ſent to Europe from La Vera Cruz, by Dr. Houſtoun[q].

48. Stem branched, even. Spines either terminating the branches, or ſolitary from the axils, ſtraight and long. Leaves lanceolate, very ſlender, ten-paired: leaflets twenty-two-paired. Spikes of flowers oblong, ovate or cylindrical, pedunculed, axillary, ſolitary. There are no prickles on the plant[r].

Native of the Eaſt Indies.

49. This tree ſeldom exceeds twelve feet in height. It has numerous branches forming a pyramidal figure. Leaves ſmall. Flowers alſo ſmall, yellow, and void of ſcent, in a cloſe cylindrical ſpike, an inch and half long. Legumes coriaceous, containing a buttery pulp, in which the ſeeds are rolled up. The ſpines are very ſingular, they are ſubaxillary and connate at the baſe, reſembling the horns of oxen; they are brown, ſhining, hollow, and the longeſt are more than five inches in length; they are all over the tree, and when the pods are ripe and the leaves are fallen, they have a ſingular appearance. A ſort of ant lodges in theſe thorns in innumerable quantities, and if the tree be ſhaken ever ſo little, they fall down like a ſhower of rain and attack the paſſenger. This tree grows every where in the woods about Carthagena; flowers in june and july, and the ſeeds ripen in ſeptember[s].]

Mr. Miller ſays the ſpines are extremely large and crooked, and of a whitiſh colour, that the flowers appear to have little beauty in them, and that the branches growing deformed, and being but thinly ſet with leaves, even in their greateſt vigour, and deſtitute of them during ſeveral months, the tree does not make a good appearance, but is chiefly ſingular on account of its writhed ſpines. He obſerves that it is rare in England. [It was cultivated in 1691, in the Royal Garden at Hampton Court[t].

50. This is a ſmall tree, growing to twelve feet in height, and one foot in diameter; it is covered with a thick rough brown bark, and towards the top divides into many cloſe branches. Leaves alternate: partial pinnæ near two inches long, commonly from fifteen to thirty pair, having ſmall glands between them: each wing has uſually about forty pairs of linear leaflets, beſet with ſhort hairs. Spines ſhort, recurved, in pairs at the baſe of each leaf. Flowers hermaphrodite and male, in cloſe axillary ſpikes, four or five inches long. Calyx tubular, hairy, dividing into five oval pointed ſegments. Corolla whitiſh, twice the length of the calyx. Filaments twice the length of the corolla, adhering at the baſe of the germ, which is oval. Pod lanceolate, brown, ſmooth, compreſſed, with an undulated thin margin. Seeds ſix or eight, roundiſh, flattened, producing a nauſeous odour when chewed.

An Indian drug, long known by the name of Terra Japonica, and now more properly called Catechu (from *Cate*, a tree, and *Chu*, juice,) is now aſcertained to be the produce of this tree. This extract in its pureſt ſtate is a dry pulverable ſubſtance, outwardly reddiſh, inwardly ſhining dark brown, tinged with a reddiſh hue: to the taſte it diſcovers conſiderable aſtringency, ſucceeded by ſome ſweetneſs. It diſſolves almoſt wholly in water, except the impurities, which are uſually ſandy, and amount to about one-eighth of the maſs. Rectified ſpirit diſſolves about ſeven-eighths into a deep-red liquor. It may be uſefully employed as an aſtringent, eſpecially in alvine fluxes; alſo in uterine proſtuvia, in debility of the viſcera in general, in catarrhal affections, &c. This extract is the baſis of ſeveral formulæ, but the beſt way of taking it is in an infuſion in warm water with cinnamon or caſſia.

Native of Indoſtan, plentifully in the mountains[u].

51. Branches angular, ſmooth, with a brown bark. Leaves ſometimes two from the axil of the ſpines: partial four or five-paired, inner ſhorter, with leaflets from five to ſeven-paired, outer eight to eleven-paired: leaflets linear, acute, ſmooth. Spines in pairs white, purple at the tip. Flowers in a globular head, axillary and ſolitary, firſt ſeſſile then pedunculed, ſhorter than the leaves. Legumes compreſſed, attenuated at the baſe[v].

Native of the Eaſt and Weſt Indies and Arabia.—Linnæus remarks, that in the American plant the heads of flowers are globular and pedunculed, as in M. tortuoſa, but that there is a minute two-valved bracte in the middle.

52. This is a large tree, with ſpreading branches, and large branched ſtraight ſcattered ſpines. Leaves unequally pinnate, commonly five-paired; with oblong-ovate, emarginate, ſmooth leaflets. Flowers pale, in long, lateral, ſcattered ſpikes: males many, more ſlender; hermaphrodites fewer, at the baſe of the ſpike. Corolla five-cleft. Stamens ten. Legume eight inches long, curved, flat, ſmooth, brown. Seeds many, ovate, compreſſed.

Native of China and Cochinchina; where it is alſo planted for hedges, which are impenetrable by animals[w].

53. This is a ſmall tree, remarkable alſo for its tremendous ſpines, at the ends of the branches, next the flowers, where there are no leaves; they are two inches long, connate at the baſe, very ſtraight, round, compreſſed as in M. cornigera, ſhining very much and whitiſh like ivory, red at the tip. The ſpines on the lower part of the ſtem are very ſhort. Leaves four-paired. Leaflets ſmall, aſh-coloured, ſix-paired. Peduncles from four to eight in the axils of the ſpines, each terminating in ſmall, yellow globules of flowers. Native of the Eaſt Indies.

54. This is a very thorny, branching, depreſſed ſhrub. Branchlets flexuoſe, interwoven, ſmooth, with whitiſh dots. Leaves very ſmall. Spines ſhining, the colour of milk, over all the branches, long, very ſtraight, divaricating. Spikes axillary, elongated, commonly in pairs, ſeldom ſolitary. Flowers white. Legume compreſſed, half-mooned.—Native of the Eaſt Indies: found by Koenig abundantly at the foot of Tripully mountain, between Tanſchu and Tirut Schinapally.

Theſe thorny Mimoſas, with their interwoven

[m] Vahl. [n] L'Heritier. [o] Hort. kew. [p] L'Heritier. [q] Mill. fig. [r] Linn. zeyl. [s] Jacquin. [t] Hort. kew. [u] Woodville, Kerr, in med. obſ. 5. 151. [v] Vahl from Forſk. [w] Loureiro.

branches

branches and terrible thorns, form impenetrable thickets in the mountainous parts of India, and are the ſecure retreat of ſmaller animals, birds and rogues [a].

55. Stem ſhrubby, branched, three feet high, covered with a reddiſh bark, rugged, very hairy, eſpecially when young, as are alſo the petioles and pedunicles. Leaves alternate: leaflets ſeventy and more, ovate-oblong, one-nerved, wider on one ſide of the baſe, and hence approximating ſo as to reſemble the leaves of Fern. Stipules awl-ſhaped, ciliate, withering. Flowers in pedicelled heads diſpoſed in a panicle. Calyx one-leafed, whitiſh, very ſmall, five-notched at top. Corolla white, with five ovate petals, double the length of the calyx. Filaments very numerous, white, in a diverging bundle, much longer than the corolla. Germ ovate-oblong, compreſſed, acuminate.

Native of Mexico. It flowered in the royal garden at Madrid in october. It approaches to M. filicifolia of Lamarck; (Dict. 1. 13.) and perhaps alſo to M. peregrina of Linneus [b].—This ſpecies ſhould have been placed after n. 43.

56. This is a ſhrub, with a branching ſtem. Branches diffuſed, ſubdivided, flexuoſe, ſmoothiſh, ſpiny, with a brown bark. Spines in pairs, almoſt united at the baſe, ſtretched out, half an inch long. Leaves three or four from one point, alternate: partial ones two-paired or three-paired: pinnas twelve to ſixteen, lanceolate, bluntiſh, entire, ſmooth. Univerſal petioles round, filiform, reddiſh; partial petioles angular. Glands ſolitary, brown, in the middle of the univerſal petioles, below the leaflets. Flowers pedunicled, in heads, yellow. Peduncles ſolitary, above the ſpines among the leaves half an inch in length, bent down. Filaments monadelphous, twenty to twenty-four, upright, yellow. Germ ovate, minute. Legume horned, roundiſh, toruloſe, drawn to a point at both ends, beaked, black. Seeds obovate, black, compreſſed a little.

Between the outer coat of the pod and the inner membrane ſeparating the ſeeds, there is a liquor of the conſiſtence and colour of a ſyrup, which ſmells very ſtrong, and is bitter and aſtringent. Browne ſays, that this would prove an excellent medicine, where rough aſtringents are requiſite. The whole plant is bitter, and the flowers have a very ſtrong ſmell [c]. Indeed the ſmell of all the parts is ſo rank and diſagreeable, that it cannot be uſed even for fire-wood. It is chiefly uſed for hedges. The cattle are ſaid to browſe upon the tender ſhoots in dry weather, and their milk thereby becomes rank.

Native of Jamaica, where it is common in the low lands, and is called the common Acacia or Acacee-buſh [d].

57. Flowers many-ſtamened, very fragrant, yellow, in ſeſſile heads [e]. Vahl ſays they are always pedunicled in the South of Europe and Barbary; and Loureiro informs us that they are ſo in Cochinchina. The petioles have a gland below the leaflets. The legumes are fuſiform [f].

Native of St. Domingo and other iſlands of the Weſt Indies, as Jamaica, Barbadoes, &c. according to Miller; alſo of Barbary, Egypt, and Cochinchina, at leaſt in a ſtate of cultivation.]

For the ſweetneſs of its flowers it has been diſperſed through moſt parts of Europe, has been made familiar to the Italian gardens, ſince it was introduced into the Farneſe garden in 1611, and is cultivated in great plenty in Spain and Portugal. The Italian gardeners, who bring over orange-trees, &c. bring alſo many young plants of this to England, under the name of Gazia. [It was cultivated in 1731, by Mr. Miller, and flowers from june to auguſt [g].]

58. This tree arrives at a large ſize in countries where it grows naturally, but in England is rarely ſeen more than eight or ten feet high. [It has the habit of M. farneſiana and Senegal; from the firſt it differs in having no callous dots upon the branches; from the ſecond, in having the bark by no means white, but purple: nor has it ſpines in threes, like M. Senegal, but in pairs, and longer than thoſe of M. farneſiana. Branches purple, even. Partial leaves about five pairs; between two pairs of the outer ones a gland is inſerted into the common petiole. Legumes necklace-ſhaped, compreſſed: the joints roundiſh-rhomb-ſhaped. Flowers many-ſtamened in peduncled heads. A gland between the outer pair of the partial leaves. Native of Egypt and Arabia. This is the tree which yields the Gum Arabic [h]. It was cultivated here in 1664 [i].

According to Haſſelquiſt, the Arabs call it Charad, and it is this, not M. Senegal, that produces Gum Arabic, Frankincenſe, and Succus Acachæ.

This ſpecies and Mimoſa Senegal growing together promiſcuouſly, the latter having by chance been brought to Europe inſtead of the former, and Proſper Alpinus not having diſtinguiſhed them, M. Senegal was generally believed to be the tree that produced the above-mentioned gums: but the genuine tree was known only to thoſe who cultivated it in Egypt, where they call the true one *Charad*, and the other, which is of no value *Feine*. They both grow in Lower Egypt, where they are planted in gardens, but they grow wild in the ſandy deſert, near the ancient ſepulchres of the Egyptians, and this, or Acacia vera is ſaid to grow plentifully in ſeveral parts of Upper Egypt. The gum is gathered in vaſt quantities from the trees growing in Arabia petræa, near the north bay of the Red Sea, at the foot of mount Sinai, whence is brought the Thus, ſo called by dealers in drugs in Egypt from Thur or Thor, which is the name of a harbour in the north bay of the Red Sea, near mount Sinai; thereby diſtinguiſhing it from the Gum Arabic, which is brought from Suez, not far from Cairo. The gum Thus is alſo more pellucid and white; whereas Gum Arabic is of a brown or dirty yellow colour and generally opaque [k].

59. Branches round, ſmooth, with a thorn on each ſide by the petiole. Leaves ten-paired: leaflets thirteen-paired, oblong, rounded at both ends, equal on both ſides. Common petiole with a pair of oppoſite recurved prickles underneath to each pair, and an upright prickle above. Peduncle axillary, a ſpan and half in length, villoſe above. Flowers in a compound raceme, numerous, ſpreading, ſcattered, on pedicels the length of the flowers. Calyx five-leaved; leaflets ovate, acute. Petals five, lanceolate. Filaments ten, diſtinct, a little longer than the corolla. Germ oblong. Style longer than the ſtamens. Stigma ſimple, blunt. Legume compreſſed, membranaceous, lanceolate.—Native of Arabia [l].

Loureiro has given the name of *ſtellata* to a ſpecies very different from this, and which Willdenow ſuppoſes may be the ſame with M. verticillata, n. 1.

60. The ſtem has recurved prickles ſcattered over it in pairs. Leaves commonly ſix-paired, with many-paired pinnas. On the univerſal petioles there are recurved prickles between each of the partial ones; and there is a ſtraight upright prickle which is longer, between each pair of the partial ones, in place of a gland. Heads globular. Legumes membranaceous-compreſſed, jointed, rugged.—Native of South America [m].]

61. This has a ſhrubby erect ſtalk about five feet high, hairy and armed with ſhort, broad, ſtrong thorns, which are white, ſtanding on each ſide, almoſt oppoſite, or alternate. Leaves five or ſix-paired, with a ſtrong midrib, and between each pair two ſhort ſtrong ſpines, pointing out each way. Leaflets extremely narrow and very cloſe. Towards the upper part of the ſtalk the flowers are produced from the ſides on ſhort peduncles; they are collected into globular heads, and are of a bright purple colour; the ſtalks are alſo terminated by ſmaller heads of the like flowers. Pods flat, jointed, about two inches long, and a quarter of an inch broad, ſpreading like rays, there being commonly five or ſix joined together at the baſe; they ſeparate at each articulation, leaving the two ſide membranes or borders ſtanding. The ſeeds, which are

[a] Linn. ſuppl. [b] Cavanilles. [c] Swartz. [d] Browne. [e] Linn. [f] Idem. [g] Hort. kew. [h] Linn. [i] Hort. kew. from Evelyn. [k] Haſſelquiſt, Engl. edit. 250. [l] Vahl. [m] Linn. amoen.

compreſſed

compreſſed and ſquare, drop out from the joints of the pods, which are hairy at firſt, but as they ripen become ſmooth. The petioles do not fall on being touched, but the leaflets cloſe up.

[Linnæus remarks, that the whole plant is rough-haired except the pinnas. The leaves often fourteen-paired, with many-paired leaflets. An upright awl-ſhaped ſpine between each pair of partial leaves; and two ſtout recurved ſolitary oppoſite ſhorter prickles between each pair of partial ones. Legume compreſſed, with ſtiffiſh pale-red hairs [a].

According to Browne, it riſes commonly to the height of ſeven or eight feet. The ſmaller branches and ribs are full of ſhort recurved thorns; and each rib again emits a number of long ſlender prickles, from the inter-ſpaces of its foliations, or ſmalleſt ribs, which, like ſo many needles, guard the tender leaves. The branches are moderately thick, but the leaves are ſmall, and very apt to move on every occaſion. The pods are compreſſed and hairy, and when ripe divide into as many parts as there are ſeeds, which fall off ſeparately; theſe parts, in the natural ſtate are held between two ribs, that run along the margins of the pod, in the inner grooves of which they move with great eaſe, when contracted and detached from each other.]

Native of Vera Cruz, where it was found by Dr. Houſtoun. [Browne ſays it was introduced into Jamaica from the main continent. Mr. Miller cultivated it before 1733.

Swartz affirms, that this and the preceding ſpecies are not diſtinct, but only varieties.

62. This is diſtinguiſhed at firſt ſight by its white bark. The ſpines at the baſe of the leaf are three, and not two, as in M. niloutica [b].

Native of Africa.

63. Leaves blunt, broad, of five, ſix or ſeven pairs of leaflets: each leaflet of from twelve to ſixteen pairs of pinnas. Gland oblong, above the baſe of the petioles. Prickles recurved, ſcattered on the ſtem and petioles. Peduncles ſimple, lateral. Panicle prickly with the flowers in heads [c].

Native of the Eaſt Indies. Introduced in 1773, by Sir Joſeph Banks [d].

64. Fruteſcent. Paniele very much branched, naked, terminating the ſtem and branches. Prickles ſmall, ſcattered over the ſtem and panicle. Leaves having from twelve to twenty pairs of partial leaves, with an oblong melliferous pore at the baſe of the general petiole. Leaflets linear and almoſt capillary. No prickles on the petioles or peduncles. A gland above the baſe of the petioles [e].

Loureiro deſcribes it as a large procumbent branching ſhrub, with many ſhort ſcattered prickles. Leaves more than ten-paired, with about forty pairs of leaflets. Flowers white, polygamous, in a vaſt diffuſed terminating panicle, of very many ſmall globular heads. Calyx four-toothed. Corolla none. Stamens above one hundred, very ſlender.

Native of the Eaſt Indies, and of Cochinchina, where the bark is converted into a ſort of tow, which is uſed for ſtopping cracks both in houſes and boats. Introduced in 1773, by Sir Joſeph Banks [f].

65. Branches obtuſe-angled, even. Prickles at the angles, recurved, ſcattered; and two, a little larger, under the ſtipules. Leaves four-paired. A gland between the loweſt partial leaves. Partial leaves twelve-paired. Pinnules blunt, curved in a little. Prickles recurved, ſcattered, under the common petiole: and rudiments of little prickles among the partial leaflets [g].

Native of the Eaſt Indies. Introduced in 1778, by Patrick Ruſſell, M. D.

66. Native of America.]

67. This has a creeping root. Stalks ſlender, having four acute angles, armed pretty cloſely with ſhort recurved ſpines. Leaves on long prickly ſtoot-ſtalks, and thinly placed on the branches. Wings two pairs, about an inch aſunder, ſhort: leaflets narrow, not very cloſe. Peduncles axillary, ſuſtaining a ſmall globular head of purple flowers. Legumes four-cornered, two inches long, four-celled, four-valved; containing ſeveral angular ſeeds in each cell.

Found at La Vera Cruz by Dr. Houſtoun, [and cultivated by Mr. Miller before 1733. It ſeems to be originally of Africa, and to have been carried to America by the ſlaves.

68. This was at firſt conſidered as a variety of M. pennata. It is ſet down by miſtake as a native of Ceylon, for it is from South America.

69. There are recurved prickles on the ſtem and petioles. Pedunckes lateral, cluſtered, headed. Legumes blunt, with a prickly ſuture.—Native of South America [h].

70. Branches with few recurved prickles. Leaves four or five-paired. A gland between the loweſt partial ones, which are twelve-paired, but the loweſt pinnule wants the oppoſite on the inſide. On the common petiole are two remote prickles, underneath between each partial ones. Stipules wide, acuminate, purple. Legumes very wide [i].—Native of America.

71. Stem ſhrubby, long, branched, prickly. Pinnas linear, many, very ſmall. Peduncles long, ſuſtaining ſmall, globular heads of flowers. Calyx ſlightly four-cleft, with rounded ſegments. Corolla none. Legume long, ſtraight, ſinuous, compreſſed. Seeds oblong, flattiſh.—Native of Cochinchina, in woods.

72. This is an arboreous ſhrub, with ſpreading unarmed branches. Leaves ſome unequally pinnate, others bigeminate: leaflets ovate, acuminate, petioled. It ſeems to be allied to M. bigemina.—Native of Cochinchina, in woods.

The bark yields excellent ſoap [k].]

73, 74, 75. Theſe are not deſcribed by Miller in his Dictionary. They were found by Houſtoun in South America.

The laſt of them is one of the moſt ſingular ſpecies yet known, the ſpines being ſpread open and flat, appearing as if ſplit lengthwiſe. The leaves are very beautiful, but the flowers being ſmall and of an herbaceous colour, make no great appearance. In the natural place of its growth this tree produces flowers almoſt through the year, and a ſucceſſion of pods is generally found on it, but the ſeeds are commonly eaten by inſects before they come to maturity [l].

[76. Trunk ill-ſhaped. Bark aſh-coloured, pretty ſmooth. Branches numerous, ſomewhat twiggy: young ſhoots winding and often bent back. Thorns ſtipular, ſuberect, ſharp, but not long. Leaves alternate, twice-double: leaflets obliquely oblong, ſmooth, pointed, about an inch long. Petioles and petiolets end in a ſharp point. Panicles terminating, thin, oblong, compoſed of diverging racemes of ſhort pedicelled ſmall globular heads of white corollets. Filaments numerous, united below into a tube. Legume ſwelled, particularly at the ſeeds, twiſted like a ſcrew, a little downy, the valves themſelves thin, almoſt membranaceous; when ripe they open naturally, and expoſe to view much roſe-coloured firm lobated fleſhy pulp, in which the black ſhining ſeeds are hid.

This is probably not a native of India, but was introduced from the Philippine iſlands, for the ſake of the pulp which fills the legumes. It grows quickly to a tree, a rich ſandy ſoil ſuits it beſt, and it flowers in the cold ſeaſon.

The fleſhy pulp of the legumes is reckoned wholeſome; it is ſweet, but inſipid and dryiſh. The Spaniards at Manilla raiſe many of the trees for the ſake of this pulp, and call it Sappan-fruit. It would aſſiſt the poor in times of ſcarcity in thoſe countries, and the gum, wood and bark may turn to account there. As it grows very faſt, it may alſo be reared for fences, inſtead of many leſs uſeful buſhes and trees.

77. Trunk ſtraight. Bark brown, pretty ſmooth. Branches numerous. Leaves ſcattered about the extremities of the branchlets, in pairs. Leaflets oppoſite, without an odd one, from two to four pairs, with a ſingle one below the pairs on the outſide: they are

[a] Linn. [b] Idem. [c] Linn. ſuppl. [d] Hort. kew. [e] Linn. ſuppl. [f] Hort. kew. [g] Hort. kew. [h] Linn. mant. [i] Linn. ſpec. [k] Linn. mant. [l] Loureiro. Mill. fig.

entire,

entire, oblong, ſmooth on both ſides; the outer pair largeſt, about five inches long and two broad; thoſe below are little more than half that ſize. Common petiole ſhort, with a large brown gland: partial petiole round, with a ſimilar gland between each pair of leaflets. Stipules lanceolate. Peduncles axillary, two to four; two to three inches long, each ending in a globular head of fragrant florets. Filaments ten, diſtinct, inſerted into the bottom of the tube. Legume broad-ſickle-form, exceedingly hard and heavy; the outſide covered with brown farina; about ſix inches long, and three broad. Seeds about ten, brown, ſmooth, each about as large as a kidney-bean.

This is one of the largeſt ſpecies of the genus. It is a native of the mountainous parts of the Circars only; caſting its leaves during the cold ſeaſon, and flowering at the beginning of the hot ſeaſon.

The wood of this tree is of a chocolate-colour towards the centre. The natives eſteem it much, and uſe it for many purpoſes, where hard durable tough timber is required; for plough-heads it is particularly in requeſt, the Telingas ſeldom uſing iron in their ploughs [a].

78. Height three or four feet. Branches alternate, upright, angular, with a very tough ſmooth bark. Leaves of the young ſeedlings in pairs and pinnated, with oval leaflets: but when the ſtem riſes, the common footſtalks of its leaves become dilated, the leaflets ceaſe to appear, and the whole ſhrub is furniſhed only with ſuch dilated naked footſtalks, which are to all intents and purpoſes leaves: they are alternate, vertical, ſmooth, firm and glaucous. Stipules none. On their upper edge near the baſe a ſmall concave gland. Racemes axillary, ſolitary, erect, of about ſix alternate heads, each having three or four ſmall white flowers. The calyx has only four ſegments, and the corolla four petals. Germ roundiſh. Pod linear, pointed, zigzag, brown, with a very thick margin. Seeds about ſix, oblong [b].

The flowers on the young branches are very numerous, and fragrant like thoſe of Spiræa Ulmaria.

Mr. Hoy raiſed it from ſeeds brought from New South Wales, in Sion gardens, belonging to his Grace the Duke of Northumberland; and it flowered there in 1790 [c]. It produced ripe pods and perfect ſeeds in the ſtove of Cheliea garden, in may 1795; but in the greenhouſe the flowers go off without any tendency to produce fruit. It is a ſhrub of quick growth and a ready blower [d].

Mr. Curtis remarks that the foliage is uſually edged with red, and that he did not obſerve the leaves to be glaucous or very much undulated.

79. The branches of this are moſt acutely triangular, and much compreſſed; their edges bright red. Leaves alternate, four or five inches long, with a rib and margin like the laſt. Flowers in axillary racemes, yelloviſh white, fragrant. Petals four. Stamens numerous. Young capſules ſmooth and glaucous.

This ſpecies and the preceding belong to the firſt diviſion of this genus, for the knowledge of which we are indebted to the ſouthern hemiſphere. In their adult ſtate they have leaves totally different from thoſe which they produce at firſt ſpringing out of the ground, as deſcribed in the preceding ſpecies. We have not any deſcription of the primordial leaves of M. ſimplicifolia, but it is probable that they alſo are pinnated.

This alſo flowered in Sion gardens under the care of Mr. Hoy, in the year 1790, from ſeeds brought from New South Wales [e].

80. This forms a thick rigid buſh. Branches numerous, alternate, ſpreading, round, very rough with a ſhort denſe rigid pubeſcence, eſpecially when young. Leaves alternate, apparently vertical, ſeſſile, pointed, entire, extremely harſh with minute prominent ſcattered points, eſpecially on the rib and the cartilaginous margin. Stipules in pairs, very minute, triangular, membranous. Flowers pale yellow, many together in little round heads, which ſtand ſolitary, on rough axillary peduncles ſhorter than the leaves, deſtitute of bracles. Calyx in four ſegments ciliated. Petals four, concave. Pod compreſſed, broadiſh in proportion to its length. It has much aſperity about it; whereas the other ſimple-leaved ſpecies are perfectly ſmooth. It is an inhabitant of Port Jackſon in New South Wales, and the living plant has not yet been introduced [f].

81. Native of Georgia and Carolina.

82. In the leaves this reſembles M. Unguis cati, but they are only one-fifth of the ſize. Legumes enſiform, compreſſed, not circinate. A gland at the baſe of the petiole, and not among the leaves.—Native of Egypt.

This ſhould have been placed after n. 10.

83. Branches round, purple, flexuoſe, pubeſcent. Leaves remote, on very ſhort petioles, very ſmooth, an inch and half long: the partial ones two-paired, the outer larger: the proper interior ones four-parted, the outer five-paired: pinnules ſeſſile, the inner ones ſmaller, oblong, narrower on the inner ſide, oblique at the baſe, mucronate, bright green, ſhining above. Gland orbiculate, ſeſſile between the partial leaves, purple edged with yellow. Petiole pubeſcent, terminated by a rigid ſpinule. Spines ſtipulary, oppoſite, ſtraight, ſpreading very much, ſtout, purple, paler at the tip. Peduncles axillary, in pairs, the length of the leaves, pubeſcent. Flowers eight to ten in each head.

Found by Koenig in the Eaſt Indies. This ſhould be placed after glauca, n. 44.

84. This is a tree, with round ſmooth dotted branches, and ſhort flexuoſe remote tubercled wrinkled branchlets. Leaves on the branches remote, alternate; on the branchlets approximating, ſubopppoſite or terminating. Leaflets eight or ten-paired: pinnules oblong, membranaceous, ſmooth, mucronate, the inmoſt ſmaller, thoſe of the terminating pair obovate, oblique at the baſe on one ſide. A ſmall gland between each pair of leaflets. Spines ſtipular, ſtraight, ſpreading very much, blunt. Peduncles on the branchlets, axillary, ſolitary, an inch and half long, ſhorter than the leaf, filiform, angular, erect. Flowers from twelve to ſixteen in an umbel. Calyx bell-ſhaped, five-toothed. Corolla one-petalled, twice as long as the calyx. Filaments numerous, very long, monadelphous. Legume involute-ſpiral, when young pubeſcent.

Found in Ceylon by Koenig.—Place after glauca, n. 44.

85. Branches purple, ſmooth, flexuoſe. Leaves uſually in pairs: partial ones three-paired, the outmoſt larger pinnate; the inner two or three-paired, in the ſecond pair four or five-paired: pinnules oval, the inner ones ſmaller. Petiole pubeſcent: a ſeſſile gland between the loweſt pair. Spines ſtipular, in threes, all ſtraightiſh, the middle one ſhorter.

It differs from M. Senegal by its purple branches, ſtraight ſpines, and fewneſs of pairs to the leaves; in that the leaves are many-paired and wider, and the petiole is terminated by a recurved prickle.

Native of Arabia [g].—This ſhould be placed after M. Senegal, n. 62.

The numerous ſpecies of Mimoſa may be diſtinguiſhed by the following circumſtances, in addition to the hints given at the foot of the generic character from Linneus, and at the head of the deſcriptions from Juſſieu. If the ſpecies had been better obſerved and deſcribed theſe diſtinctions might have been more perfect.

Leaves ſimple in N. 1, 2. 78, 79, 80.
- pinnate in N. 3 to 8. and 77.
- bigeminate in N. 9 to 11. 76. 82.
- conjugate and at the ſame time pinnate in N. 12 to 20.
- bipinnate in the reſt. N. 21 to 75. 81. 83 to 85.

Unarmed, or without thorns or prickles. N. 1 to 9. 11 to 13. 15. 21 to 39. 41. 43 to 47. 55. 72. 74. 77 to 80.

Armed. N. 10. 14. 16 to 20. 40. 42. 48 to 54. 56 to 71. 73. 75. 76. 81 to 85.

Moſt of the ſpecies have Stipules, as N. 24, 25. 30. 45. 49 to 59. 65. 70. 76. 80. 83 to 85.
Some however have no Stipules, as N. 2. 10. 78.
The greater part have Glands, chiefly on the petioles of the leaves, as N. 4. 10. 14. 27. 29, 30. 33. 38. 40. 43. 45. 56. 58. 63 to 65. 70. 77, 78. 83 to 85.
The following have no Glands. N. 6. 22. 24. 25. 32.
The Flowers are moſtly hermaphrodite and male or ſometimes female on one plant; in a few ſpecies however they appear to be all perfect, as in n. 30. but they are probably not really ſo, ſince few of them produce fruit.
Calyx commonly five-toothed or ſlightly five-cleft. In ſome ſpecies however it is
Five-leaved, as in n. 59. Or
Four-toothed, as in N. 36. 64. 71. 78 to 80.
Trifid, in N. 20.
Corolla commonly one-petalled, and five-cleft. But
Five-petalled in N. 59.
Four-petalled in N. 36. 78 to 80.
None in N. 19, 20. 44. 64. 71.
White in N. 6 to 8. 10. 29. 33. 35. 36. 40, 41. 44. 54, 55. 64. 76. 78.
Greeniſh White, 4. 21, 22.
Yelloviſh White, 79.
Yellow, 20. 23. 26, 27. 53. 56, 57. 80.
Purple, 11, 12. 19. 47. 61. 67.
Stamens in the greater part many: and of theſe
Monadelphous, 4. 7. 9 to 11. 29, 30. 36. 56. 76. 84.
Four in N. 20.
Five in N. 19.
Ten in N. 18. 22. 26, 27. 44. 52. 59. 77.
Legume opening or two-valved in moſt.
Not opening, in N. 20. 30. 57. 61.

The following ſpecies are Senſitive or yield to a ſlight force more or leſs. *Pudica, viva, caſta, plena, punctata, aſperata, ſenſitiva, quadrivalvis.*]

PROPAGATION AND CULTURE.

Of Senſitive and Humble Plants.

Theſe plants are all of them propagated by ſeeds, which ſhould be ſown early in the ſpring, upon a good hot-bed. If the ſeeds are good, the plants will appear in a fortnight or three weeks, when they will require to be treated with care, for they muſt not have much wet till they have acquired ſtrength; nor ſhould they be drawn too weak, ſo that freſh air ſhould be admitted to them at all times when the air is temperate. In about a fortnight or three weeks after the plants come up, they will be fit to tranſplant, eſpecially if the bed in which they were ſown, continues in a proper degree of heat; then there ſhould be a freſh hot-bed prepared to receive them, which ſhould be made a week before the plants are removed into it, that the violent heat may be abated before the earth is laid upon the dung, and the earth ſhould have time to warm before the plants are planted into it. Then the plants muſt be carefully raiſed up from the bed to preſerve the roots entire, and immediately planted in the new bed, at about three or four inches diſtance, preſſing the earth gently to their roots; then they ſhould be gently ſprinkled over with water, to ſettle the earth to their roots; after this they muſt be ſhaded from the ſun till they have taken new root, and the glaſſes of the hot-bed ſhould be covered every night to keep up the heat of the bed. When the plants are eſtabliſhed in their new bed, they muſt have frequent, but gentle waterings; and every day they muſt have free air admitted to them, in proportion to the warmth of the ſeaſon, to prevent their being drawn up weak, but they muſt be conſtantly kept in a moderate degree of heat, otherwiſe they will not thrive. In about a month after the plants will be ſtrong enough to remove again, when they ſhould be carefully taken up, preſerving as much earth to their roots as poſſible, and each planted in a ſeparate ſmall pot, filled with good kitchen-garden earth, and plunged into a hot-bed of tan, carefully ſhading them from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender exotic plants from very warm countries.

The ſorts which grow upright and tall, will ſoon riſe high enough to reach the glaſſes of the hot-bed, eſpecially if they thrive well; therefore they ſhould be ſhifted into larger pots, and removed into the ſtove, and if they are plunged into the tan-bed there, it will greatly forward them.

The perennial ſorts will live through the winter, if they are preſerved in a warm ſtove, and the following ſummer they will produce flowers and ripen their ſeeds. Some of theſe may be propagated by laying down their branches, which will put out roots, and then may be ſeparated from the old plants; and I have ſometimes propagated them by cuttings, but the plants which riſe from ſeeds are preferable to either of theſe.

There is no particular management which theſe plants require, different from others of the ſame warm countries; the great care muſt be to keep them in a proper temperature of heat, and not to give them too much water, eſpecially in cool weather; nor ſhould they be kept too dry, for many of the ſorts require frequent waterings, as they naturally grow in moiſt places. There ſhould alſo be care taken that they do not root into the tan-bed, for they ſoon put out their roots through the holes at the bottom of the pots, which, when they ſtrike into the tan, will cauſe the plants to grow very luxuriant; but when they are removed, and theſe roots are cut or broken off, the plants ſeldom ſurvive it; therefore the pots ſhould be frequently drawn out of the tan, and if any of the roots are beginning to get through the holes at the bottom, they ſhould be cut off cloſe; and when the roots are very cloſely matted together, they ſhould be turned out of the pots, and pared round to reduce them, and then potted again, either in pots of the ſame ſize, or if the plants require, in pots one ſize larger; but they muſt not be over-potted, for then the plants will not thrive.

Some of thoſe ſorts whoſe ſtalks ſpread near the ground, may be turned out of the pots in the middle of June, and planted in a very warm border, where, if they are covered with bell or hand-glaſſes, they will live through the ſummer; but theſe will not grow very large, and upon the approach of cold in the autumn, they are ſoon deſtroyed: however, thoſe who have not conveniency of ſtoves or tan-beds, may raiſe the plants on common hot-beds in the ſpring, and when they have acquired ſtrength, they may be treated in this manner, whereby they will have the pleaſure of theſe plants in ſummer, though not in ſo great perfection, as thoſe who have the advantages before-mentioned: but theſe plants will not thrive in the open air in this country, nor will they retain their ſenſibility when they are fully expoſed to the air.

Propagation and Culture of Acacias.

Theſe being all tender, are to be placed in ſtoves in the winter, and in ſummer muſt be but a ſhort time expoſed to the open air, and have a warm ſituation.

They are propagated by ſowing their ſeeds on a hot-bed in the ſpring of the year, which will in a ſhort time appear above ground, and in about five or ſix weeks after, be fit to tranſplant, when a freſh hot-bed is to be prepared for them, and ſhould be pretty warm; the next thing to be provided is a quantity of ſmall halfpenny pots, which are to be filled with freſh, light, ſandy earth; theſe ſhould be plunged into the hot-bed, but not into dung; for if theſe beds are made with warm horſe-dung, they ought to be covered with earth as deep as the pots, whoſe bottoms ſhould reſt upon the dung, for otherwiſe the roots of the plants may ſuffer by too much heat; but beds of tanners bark ſeldom heat ſo violently. As ſoon as the earth in the pots is warm, which will be in two or three days, you ſhould carefully take up the young plants out of the firſt hot-bed, planting four or five plants into each of theſe pots, giving them a gentle watering to ſettle the earth to their roots, and ſcreening them with mats over the glaſſes from the heat of the ſun, until they have taken root; after which time you muſt give them air, by raiſing the glaſſes in proportion to the heat of the weather, or to the conſtitution of the plants.

The

The 49th, 57th, and 58th ſorts are very tender, eſpecially while young, therefore ſhould have a hot-bed of tanners bark; and as they increaſe in bulk, ſhould be ſhifted into bigger pots. The earth for theſe ſhould be a little lighter, and more inclined to a ſand, than for the other ſorts; but never plant them in pots that are too large, which is full as bad to theſe as to Orange-trees; neither give them too much water, eſpecially in winter. The 58th ſort being the hardieſt of the three, will, when grown to be woody, ſtand in a common ſtove, which ſhould be kept to the point of temperate heat in winter; and in the ſummer time, in warm weather, may enjoy the open free air: but the two other ſorts muſt have a bark-ſtove in winter; nor ſhould they be expoſed to the open air in ſummer, at leaſt for four or five years, until they are grown very woody, for they are very tender, and with great difficulty preſerved in this climate. The ſtove in which theſe ſhould be placed in winter, muſt be kept above the temperate point, as marked in the botanical thermometers. Theſe ſhould have very little water in winter, but in ſummer time will require frequent refreſhings, though at that ſeaſon it ſhould not be given them in great quantities at one time. The 57th ſort is a very beautiful tree. The 49th ſheds its leaves juſt before the new ones come on, ſo that it is naked of leaves about a month or ſix weeks in the ſpring of the year, which has occaſioned ſome people to throw them away as dead, when, if they had let them remain, they would have come out freſh again.

This I thought proper to mention, in order to caution people not to be too haſty in throwing out trees for dead, but preſerve them through the ſucceeding ſummer, to ſee if they will ſhoot again; for I have known ſeveral plants, which, after having been given over by unſkilful perſons for dead, have the July following ſhot out vigorouſly again; and others, which have died to the ſurface of the earth, have riſen again from the root.

The horned Acacias are very often deſtitute of leaves for two or three months, appearing to have no life; but they will put out freſh leaves towards autumn, which is commonly the ſeaſon when they are moſt vigorous. Theſe ſhould be expoſed in the ſummer ſeaſon for about two months, to clear them from inſects, which greatly inſeſt them, in a place defended from ſtrong winds; and in the winter they require a moderate degree of warmth.

All the other ſorts here mentioned are propagated by ſeeds, which, ſeldom ripening in this country, muſt be procured from America, particularly at Campeachy, where there is great variety of this tree, many ſorts of which have been hitherto unknown to botanical writers. In bringing over the ſeeds of theſe trees, they ſhould be taken out of the pods when gathered, and put up in papers, and ought to have Tobacco, or ſome other noxious herb, put between the papers, to keep off inſects, otherwiſe the ſeeds will be eaten and deſtroyed before they arrive in England. For the inſects depoſit their eggs in ſmall punctures which they make in the pods; and as theſe are ſoon hatched, ſo they immediately attack the ſeeds for food, and eat holes through them, by which they are ſpoiled from growing. This has often happened to ſeeds which have been ſent me from America.

There are ſeveral of theſe Acacias, which are very tender while they are young; but, after two or three years growth, become hardy enough to bear the open air in ſummer, though ſcarce any of them will live through the winter in a green-houſe, unleſs they have ſome warmth in very cold weather.

MIMOSA. See *Aſchynomene*.

MIMULUS (*of Pliny*, Mimus perſonatus, *ſo named from its ringent corolla.*)

Lin. gen. n. 783. *Reich. n.* 846. *Schreb. n.* 1049. *Gærtn. t.* 53. *Juſſ.* 122. Cynorynchium. *Mitch.* 3.

Claſs. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ*. *Scrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, oblong, priſmatic, five-cornered, five-folded, five-toothed, equal, permanent.

COR. one-petalled, ringent. *Tube* the length of the calyx. *Border* two-lipped. *Upper lip* upright, bifid, rounded, bent back at the ſides. *Lower lip* wider, trifid, with the ſegments rounded: the middle one ſmaller. *Palate* convex, bifid, protruded from the baſe of the lip.

STAM. *Filaments* four, filiform, within the throat: two ſhorter. *Anthers* bifid-kidney-form.

PIST. *Germ* conical. *Style* filiform, the length of the ſtamens. *Stigma* ovate, bifid, compreſſed.

PER. *Capſule* oval, two-celled, opening tranſverſely at top. *Partition* membranaceous, contrary to the valves.

SEEDS very many, ſmall. *Receptacle* oblong, faſtened on each ſide to the partition.

ESSENTIAL CHARACTER.

Cal. four-toothed, priſmatical. *Cor.* ringent: the upper lip folded back at the ſides. *Capſ.* two-celled, many-ſeeded.

Stem erect ſhrubby round, leaves ovate-lanceolate blunt iſh.]

DESCRIPTIONS, &c.

1. Root perennial. Stalk annual, ſquare, a foot and half high, with two oblong ſmooth leaves at each joint, broadeſt at their baſe, where they join round the ſtalk, but ending in acute points. The lower part of the ſtalk ſends out two or three ſhort branches, and the upper part is adorned with two flowers at each joint, from the boſom of the leaves on each ſide; they are of a violet colour, and have no ſcent [Capſule clothed with the five-cornered calyx, oval, two-celled. Receptacle ſpongy, hollow-dotted. Seeds ovate-oblong, ſmooth, pale ſtraw-colour, ripped at each end with a ſmall prominent ruſeſcent point[a].

Native of Virginia and Canada. Cultivated in 1759 by Mr. Miller. It flowers in July and auguſt[b].

2. Native of Peru[c].

3. This has the appearance of the firſt ſpecies. Stem winged with four membranes running down from the baſe of the petioles, ſimple, ſmooth, with a branchlet or two at top. Leaves two inches long, veined, unequally ſerrate. Peduncles axillary, ſolitary, oppoſite, four-cornered, thickened at top. Calyx the length of the peduncle, with rounded mucronate ſegments. Corolla a little longer than the calyx[d].

Native of North America. Introduced in 1783, by Mr. William Malcolm. It flowers in July and auguſt[e].

4. Stalk about three feet high, much branched, ſhrubby, round, the young wood green, with a tinge of purple towards the lower part of each joint, ſlightly viſcid, as it becomes older changing to a light-brown colour, and diſcovering manifeſt fiſſures: branches alternately oppoſite, flower-bearing quite to the baſe. Leaves oppoſite, ſeſſile, ſlightly connate, the bluntneſs at the end particularly apparent when contraſted with a leaf of the firſt ſpecies, toothed or ſlightly ſerrate, ſmooth, veiny. Flowers inodorous, large, nearly twice the ſize of thoſe of the ringens, uniformly pale orange, growing in pairs from the axils of the leaves, on peduncles that are about half the length of the calyx. Tube of the corolla within the calyx narrow, cylindrical, pale yellow, bent a little downwards, gradually ſpreading. Segments of the lips irregular, the

[a] Gærtner. [b] Hort. Kew. [c] Linn. [d] Vahl. [e] Hort. kew.

two uppermoſt very much ſo; at the baſe of the middle ſegment of the lower lip are two prominent ridges, of a ſomewhat deeper colour. Anthers deep orange, cruciform, within the flower. Stigma white, two-lipped, with the lips cloſed or expanded according to its age. Germ oblong, with a gland at the baſe of conſiderable ſize which ſecretes much honey. It flowers during moſt of the ſummer. Cultivated by Mr. Colvill, nurſery-man in the King's-road near Cheliea in 1796 [1].

PROPAGATION AND CULTURE.

1. This plant is very hardy in reſpect to cold, but ſhould have a loamy ſoft ſoil, rather moiſt than dry, and not too much expoſed to the ſun. It may be increaſed by parting the roots in autumn; but they ſhould not be divided too ſmall. It may alſo be propagated by ſeeds ſown in autumn, ſoon after they are ripe; for thoſe which are ſown in the ſpring ſeldom grow the ſame year: they ſhould be ſown on a border expoſed to the morning ſun.

[The third ſort may be increaſed in the ſame way; and the fourth by cuttings.

MIMULUS. See *Rhinanthus*.

MIMOSOPS. (*From μιμος a monkey, and οψις, a face: ſo named on account of the form of its corolla.*)

Leaves alternate, obovate, emarginate.

[1] Curtis.

DESCRIPTIONS, &c.

1. This is a middle-ſized tree, with petioled, oval, acute, quite entire, ſmooth leaves. Flowers axillary, on very many ſimple pedunculs. Calyxes tomentoſe [2]. Berry ſuperior, ovate, defended at the baſe by the permanent calyx, having an obſolete groove on one ſide, ſhagreened all over with very minute callous dots, fleſhy, thick. Seed one, fixed to the bottom of the cell, ovate-oblong, contracted near the baſe into a ſhort thick point, compreſſed like a lens, or flatiſh at the ſides, but keeled at the edge, very ſmooth, of a yellow-bay colour [3].

Native of the Eaſt Indies, where it is much planted on account of its fragrant flowers, which come out chiefly in the hot ſeaſon.

2. This is a tree with thicker branches, having ſmall ſcars ſcattered all over them. Leaves at the ends of the branches only. Flowers like thoſe of the preceding [4].

Linnæus, in his earlier works, having made no mention of the nectaries, Forſkahl took this for a diſtinct genus, and named it Binectaria. He has deſcribed it well [5].

Native of the Eaſt Indies, and Arabia.

Juſſieu, from Commerſon's manuſcripts, and after him Gmelin, made a diſtinct genus of this, under the name of Imbricaria, on account of its fruit having eight cells and as many ſeeds: but Commerſon obſerved that four or more of theſe were often abortive; and on the other hand Rumphius tells us that the Mimuſops has often as many as three or four perfect ſeeds. It is probable therefore that the germ has eight cells and eight ſeeds, moſt of which are generally abortive [6].

3. This is a large tree with an erect trunk, and covered with an aſh-coloured bark. When old it has frequently large rotten excavations. Branches numerous, ſpreading; the extremities nearly erect, forming a large ſhady head. Leaves broad, wedge-form or inverſe-hearted, deeply emarginate, very hard, deep ſhining green on both ſides, three to five inches long, an inch and half or two inches wide. Petiole round, an inch or an inch and half long. Pedunicles axillary, from one to ſix, erect or ſpreading, nearly as long as the petiole, clubbed, undivided, one-flowered. Flowers conſiderably ſmaller than in the firſt ſort. Calyx ſix-leaved; three leaflets interior, three exterior and leathery. Corolla one-petalled: tube very ſhort; border of two rows of ſegments, the exterior twelve, the interior ſix, all ſpreading. Nectary eight-leaved, conical, ragged, hairy near the baſe, inſerted alternately with the filaments into the mouth of the tube, ſpreading, ſhorter and more deeply indented than in the firſt ſort. Filaments ſix, ſpreading. Anthers oval. Berry ovate, the ſize and ſhape of an Olive, with generally one ovate, compreſſed, ſmooth, ſhining, cheſtnut coloured ſeed.

Native of the Eaſt Indies, in the mountainous uncultivated parts of the Circars. The wood being remarkably heavy, is much uſed by the wathermen to beetle their cloth on [7].

MINDIUM. See *Mnium*.

MINT. See *Mentha*.

MINUARTIA. (*So named from Minuartus an apothecary, reſtorer of botany in Spain; he conſtituted the genus* Cerviana, *now* Pharnaceum, *and is commended by Loefling.*)

PER. *Capsule* oblong, triangular, much shorter than the calyx, one-celled, three-valved.

SEEDS some, roundish, compressed.

OBS. M. montana *has five petals; scarcely any; and commonly five stamens, like* Alsine.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* none. *Capf.* one-celled, three-valved. *Seeds* some.

SPECIES.

1. Minuartia dichotoma.
Lin. fpec. 132. *fyft.* 130. *Reich.* 1. 249. *Act. holm.* 1758. *t.* 1. *f.* 4. *Loefl. it.* 121. *t.* 1. *f.* 5.
Flowers clufered dichotomous.

2. Minuartia campeftris.
Lin. fpec. 132. *fyft.* 130. *Reich.* 1. 249. *Loefl. it.* 122. *Act. holm.* 1758. *t.* 1. *f.* 3.
Flowers terminating alternate longer than the bractæ.

3. Minuartia montana.
Lin. fpec. 132. *fyft.* 130. *Reich.* 1. 249. *mant.* 328. *Loefl. it.* 122. *t.* 1. *f.* 4.
Flowers lateral alternate fhorter than the bractæ.

DESCRIPTIONS, *&c.*

Thefe are all annual plants, natives of Spain. Leaves oppofite, cluftered. Flowers in cluſters, with five or three very fmall petals, like glands*.

1. This is a rigid, hard, tough little plant, commonly fimple. Leaves briſtle-fhaped. Flowers ſeſſile in cymes, forming a ſquare head, cluſely dichotomous, ſaſtigiate, commonly larger than the ſtem. Bractes briſtle-fhaped, longer than the flowers, with a ſtraight tip. Seeds five to eight, roundiſh, kidney-form. Colour of the plant ſomewhat duſky.
Native of Spain*.

2. Native of Spain, in the lower hills.

3. Stems ſeveral, diffuſed, a finger's length, ſub-pubeſcent and hoary. Branches ſimple, lateral, very ſhort, alternate. Leaves awl-ſhaped, pubeſcent, connate at the baſe, the length of the branches. Balls of flowers lateral, ſeſſile, among the longer leaves. Calyx awl-ſhaped, erect, ſcarcely ever ſpreading. Petals five, ſo ſhort as to be ſcarcely any. Stamens often five, like thoſe of Alſine, very ſhort. Styles three, white, recurved, blunt. Germ oblong. Linnæus doubts whether it ought not to be referred to the genus Alſine†, and recommends a compariſon of it with Alſine mucronata in its native ſoil. The ſtructure of that is ſimilar to this, but it is looſe, very much branched and diffuſed, whereas M. montana is contracted‡.

MIRABILI AFFINIS. See *Baſella.*]

MIRABILIS. *(So named from the wonderful diverſity of colours in the flower. For the ſame reaſon it is called in Engliſh* Marvel of Peru. *Every thing from the New Continent was at firſt eſteemed wonderful.)*
Lin. gen. n. 242. *Reich.* n. 259. *Schreb.* n. 283. *Gærtn. t.* 127. Nyctago *Juſſ.* 90. Jalapa *Tournef. t.* 50.

CLASS. 5. 1. Pentandria Monogynia.

NAT. order of *Nyctagines* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth outer* one-leafed, erect-ventricoſe, inferior, five-parted: *ſegments* ovate-lanceolate, ſharp, unequal, permanent. *Inner* globular placed under the petal, with a contracted entire mouth, and permanent.

COR. one-petalled, funnel-form. *Tube* ſlender, long, thicker at top, placed on the inner calyx. *Border* from upright ſpreading, entire, bluntly five-cleft, plaited.

Nectary ſpherical, fleſhy, ſurrounding the germ, with a five-toothed mouth: teeth very ſmall, triangular, converging.

STAM. *Filaments* five inſerted into the orifice of the nectary, and alternate with its teeth, within the inner calyx free, more ſlender, faſtened at bottom to the tube of the corolla, filiform, the length of the corolla, inclining, unequal. *Anthers* twin, roundiſh, riſing.

PIST. *Germ* turbinate, within the nectary. *Style* filiform, the length and ſituation of the ſtamens. *Stigma* globular, dotted, riſing.

PER. none. The inner Calyx incruſts the ſeed and falls with it.

SEED ſingle, ovate-five-cornered.

OBS. *Some toothlets of the nectary are commonly obſolete.*

ESSENTIAL CHARACTER.

Cal. inferior. *Cor.* funnel-form, ſuperior. *Nect.* globular, incloſing the germ.

DESCRIPTIONS, *&c.*

Root tuberous. Stem herbaceous, round, often trichotomous. Leaves oppoſite. Flowers terminating, in a ſort of corymb. Outer calyx bell-ſhaped-ſpreading, five-cleft: inner (which is the corolla of Tournefort and Linnæus) large, petaloid, funnel-form, ventricoſe at the baſe, beyond that contracted, dilated above with a ſpreading border, almoſt entire or five-toothed. Germ half covered with an ambient gland (which is the tube of the filaments coaleſcing at the baſe, according to Adanſon). Stamens inſerted into the gland and glued to the calycine tube. Seed globular, covered with the coriaceous baſe of the inner calyx. This genus is allied to the Amaranthi and Caryophylleæ by its farinaceous ſeeds; to the Dipſaceæ in its habit and double calyx: it differs however in many marks, and it is difficult to aſſign it a place*. Hence Linnæus left it among the plants of doubtful rank, in his Ordines Naturales.

γ. Flowers terminating, about ſix, cloſe together without any leaflets between them, and not longer than the leaf*.

It is a perennial plant, and the roots in their native country acquire a great ſize.]

Of this there are ſeveral varieties in the colour of the flowers (purple or red, white, yellow, variegated

* Juſſieu. † Linn. ſpec. ‡ Linn. mant.
* Item. ſyſt. and Act. holm.
* Juſſieu. † Linn. ſpec.

purple and white, and variegated purple and yellow.) Theſe reſolve themſelves into two principal varieties; the firſt of which has purple and white flowers, which are variable; ſome are plain purple, others plain white, but moſt of them are variegated with the two colours, and all are found ſometimes on the ſame plant: the ſecond has red and yellow flowers, generally mixed, but ſometimes diſtinct on the ſame plant: ſome plants have only plain flowers, others only variegated, and others again both plain and variegated: but plants raiſed from the ſeeds of the purple and white never produce red and yellow flowers, nor the contrary.

Theſe varieties are very ornamental plants in the flower garden during the months of july, auguſt and ſeptember, and if the ſeaſon ſhould continue mild, they often laſt till near the end of october. The flowers do not open till towards the evening, whilſt the weather continues warm, but in moderate cool weather, when the ſun is obſcured, they continue open almoſt the whole day. They are produced ſo plentifully at the ends of the branches, that when they are expanded the plants ſeem entirely covered with them, and ſome being plain, others variegated on the ſame plant, they make a fine appearance.

[It is a native both of the Eaſt and Weſt Indies, China, Cochinchina and Africa, but was introduced into Europe firſt from Peru. It was cultivated here by Gerarde many years, as he ſays, before the publication of his Herball in 1597. Parkinſon is very diffuſe in his deſcription of this plant in his Paradiſus, or Garden of pleaſant flowers, publiſhed in 1629, and was well acquainted with its ſeveral varieties.

Thunberg informs us, that the Japoneſe ladies make a white paint from the meal of the ſeeds, for their complexions.

2. This reſembles the preceding very much.] The ſtalks have thick ſwollen joints: the leaves are ſmaller; the flowers are not much more than half the ſize of the other, and do not vary in their colour from their natural purpliſh red; the fruit is very rough. It is a native of Mexico, but is very common in all the iſlands of the Weſt Indies, where the inhabitants call it the Four o'clock flower, from the flowers opening at that time of the day.

Tournefort was informed by Plumier that the root of this plant is the officinal Jalap; but Dr. Houſtoun was fully informed of the contrary in the Spaniſh Weſt Indies, and brought over a drawing of the plant made by a Spaniard at Halapa or Xalapa, and carried ſome of the plants to Jamaica, where they were deſtroyed by hogs. He was however fully ſatisfied of its being a Convolvulus, as Mr. Ray had ſaid many years before, upon what authority it does not at preſent appear. Mr. Miller, a few years after, (viz. in 1736) received three ſeeds of the Jalap from the Spaniſh Weſt Indies, one of which grew, and became a large plant, having a bulbous (tuberous) root, as large as that of the Jalap commonly imported, but the plant produced no flowers in the three years it lived. The ſevere winter of 1739-40 killed it. The roots of Marvel of Peru are indeed purgative, like Jalap, given in a double doſe, but it is now generally ſuppoſed that the true Jalap is a ſpecies of Convolvulus. [Loureiro however affirms that M. Jalapa produces the true Jalap. See Convolvulus Jalapa. It was introduced before 1728, by Charles Du Bois Eſq.]

3. The ſtalks of this ſort fall on the ground, if they are not ſupported; they grow about three feet in length, and divide into ſeveral branches; they are hairy and clammy. The flowers come out at the ends of the branches, are white, have very long ſlender tubes, and a faint muſky odour: as in the other ſpecies, they are ſhut during the day, and expand as the ſun declines. The ſeeds are larger than thoſe of the other ſpecies, and are as rough as thoſe of the ſecond.

[Gærtner thus deſcribes the parts of fructification. Floral involucre five-leaved, ſpreading bell-ſhaped. Calyx one-leafed, globular, toothleſs, continuous with the corolla, permanent, ſerving as an involucre to the ſeed. Corolla one-petalled, five-cleft. Stamens from the bottom of the corolla, connate at the baſe. Germ within the calyx, placed on the receptacle of the ſtamens. Seed involucred with the hardened calyx, ovate-globular, ſmooth, the colour of honey or ruſſet-cent, marked on one ſide with a longitudinal faſcia from the protuberant radicle of the embryo. Pericarp none, except the calyx be called ſo, which is hardened into a coriaceous ovate nut, contracted at the baſe, obſcurely five-cornered, ſomewhat wrinkled, pubeſcent, clouded with aſh-colour and brown, and marked within by five longitudinal bands, from the preſſion of the ſtamens.

Native of Mexico. Cultivated [in 1759 by Mr. Miller.] who ſays, that the ſeeds were firſt ſent him from Paris by Dr. Mounier, and afterwards from Madrid by Dr. Ortega. [It flowers, as the common ſort does, from june to ſeptember.

4. Stems thick, round, ſwelling at the joints, with oppoſite branches, three or four feet high. The whole plant villoſe-glutinoſe. Leaves thick, glaucous, quite entire, with the border uſually waving, a ſhort nap on the upper ſurface, very villoſe underneath, the hairs terminated by a very ſmall glutinoſe gland; petioles ſhorter than the leaf. Flowers in oppoſite axillary racemes. Calyx bell-ſhaped, inferior, half-five-parted, with the ſegments preſſed cloſe, whilſt the corolla remains ſmall, but after that falls increaſing, and appearing at firſt yellow and five-cornered, but afterwards expanded into a flat ſmooth brown membranaceous five-cornered five-rayed pelta, with nerved rays in the centre of which is placed the fruit. Corolla ſuperior, violet-coloured: tube ſhort, marked externally with five awl-ſhaped, green lines: border ſpreading, ten-notched. Stamens three or four, violet, longer than the corolla, arched at top, inſerted into the apex of the germ which is ſomewhat hollow under very ſmall ſcales. Germ at the bottom of the calyx and below the corolla, ovate, five-ſtreaked. Style longer than the ſtamens, arched. Stigma with many pedicelled mamillæ. Fruit a one-ſeeded nut in the centre of the expanded calyx, ovate, five-cornered, with longitudinal warted grooves.

Native of Huanuco in Peru. It flowered in the royal garden at Madrid from auguſt to december.

Cavaniles numbered three and ſometimes four ſtamens in the cultivated plant: it ſhould be enquired whether the one be the ſame in the wild plant.]

PROPAGATION AND CULTURE.

Sow the ſeeds on a moderate hot-bed in march. When the plants come up admit plenty of air to them, when the weather is mild. When they are two inches high tranſplant them on another very moderate hot-bed, or plant each in a ſmall pot filled with light earth, and plunged into a hot-bed, whence they may be ſhaken out into the borders with more ſecurity.

When they are in the ſecond hot-bed, they ſhould be ſhaded till they have taken freſh root, after which they muſt have plenty of free air; and in may they muſt be gradually inured to the open air. The beginning of june, if the ſeaſon be favourable, tranſplant them into the borders of the pleaſure-garden, giving them proper room; and after they have taken new root, they will require no farther care. If the ſeeds be ſown in a warm border the beginning of april, they will grow very well, but the plants will be late in the ſeaſon before they flower.

As the ſeeds ripen very well, there are not many perſons who are at the trouble of preſerving the roots: if theſe however be taken out of the ground in autumn, and laid in dry ſand all the winter, ſecured from froſt, and planted again in the ſpring, they will grow much larger, and flower earlier than the ſeedling plants: or if the roots be covered in winter with tanners bark to keep out the froſt, they may remain in the borders, provided the ſoil be dry. If the roots which are taken out of the ground, be planted the following ſpring in large pots, and plunged into a hot-bed, under a deep frame, they may be brought forward, and raiſed to the height of four or five feet, and come earlier in the ſeaſon to flower.

[1] Linn. ſpec. [2] Hort. kew. [3] Gærtner [4] Hort. kew. [5] Cavaniles.

In the choice of the ſeeds care ſhould be taken not to ſave any from the plants with plain flowers; and in order to have variegated flowers, the plain flowers ſhould be pulled off from thoſe plants which are intended for ſeed.

The ſecond ſort is not quite ſo hardy as the firſt and third, ſo that unleſs the plants are brought forward in the ſpring, they will not flower till very late, and their ſeeds will not ripen.

DESCRIPTIONS, *&c.*

1. Root perennial, from which come out many heart-ſhaped angular leaves, ſome of which are obtuſe, and others end in acute points; they are indented on their edges, of a lucid green, a little hairy, and ſtand upon pretty long foot-ſtalks. The flower-ſtalks ariſe immediately from the root, having two or three angular leaves towards the bottom, and about the middle of the ſtalk come out two ſmall leaves with acute angles, placed oppoſite. The ſtalks riſe eight or nine inches high, and are terminated by a looſe ſpike of ſmall whitiſh flowers, the petals of which are fringed on their edges. They appear the beginning of june. Native of moſt parts of North America, in woods.

2. This is of humbler growth, ſeldom riſing more than five or ſix inches high. The leaves are not ſo angular as thoſe of the firſt ſort, the flower-ſtalks are always naked, the ſpikes of flowers ſhorter and more compact.

Native of the northern parts of Aſia. Both theſe were cultivated by Mr. Miller in 1731.

PROPAGATION AND CULTURE.

Theſe plants are increaſed by parting the roots in autumn. They love ſhade, and a ſoft loamy ſoil.

MITELLA. See *Bixa*, and *Tiarella*.

MITHRIDATEA. (*So named by Commerſon in memory of Mithridates, King of Pontus, famous in the old Materia Medica, and for his knowledge of poiſons.*)

SPECIES.

1. Mnasium paludosum.

Gmel. syst. 533.

Rapatea paludosa. *Aubl. guian.* 1. 305. *t.* 118.

DESCRIPTION, *&c.*

This is a perennial plant, with a fibrous, woody root; the leaves are very long, narrow, sharp, smooth, striated, perfectly entire, sheathing at the base and mutually embracing each other, and are narrowed above the sheath. The stalks are several, naked, two feet high, striated, compressed, margined, gradually dilating towards the top, and springing from the bosoms of the radical leaves. The flowers are collected within an involucre, and are pedunculated: the peduncle is imbricated with scarcely perceptible scales beneath the base of the calyx. The corolla is yellow.

Native of Guiana, growing in marshy woods.

Mniarum bifforum.

Lin. suppl. 81. *Syst.* 53. *Willd.* 30. *Forst. prodr.* 2. 6. *comm. got.* 9. 19. *t.* 1.

DESCRIPTION, *&c.*

This plant resembles Mnium in so much in its appearance, that without examining the flower, it would be ranked with that genus. It is very smooth, dichotomous, covered all over with approximating, acerose, connate leaves. Flowers terminating in pairs, subsessile, generally shorter than the leaves. Native of New Zealand and Terra del Fuego*.

MNIUM. (*Adopted from the Greek* Μνιον *by Dillenius.*)

Lin. gen. n. 1193. *Reich. n.* 1310. *Dill. muſc.* 329. *Hedw. ſtirp. t.* 37.

Class. 24. 3. Cryptogamia Musci.

Nat. order of *Musci.*

GENERIC CHARACTER.

Capsule with a lid. *Calyptra* smooth. Briſtle from a terminating tubercle. *Male flowers* headed or discoid.

Or thus, from Withering.

Caps. with a veil: *fringe* with fifteen teeth; sometimes though rarely with four.

Male. Bud circular, rarely knob-like, mostly on a separate plant.

In the 14th edition of Systema Vegetabilium twenty species of Mnium are enumerated. Dr. Withering has twenty-four British species, besides many varieties, in the third edition of his Botanical Arrangement. Figures of these may be seen in Dillenius, Hedwig, Vaillant, Micheli, Morison, Dickson, &c.

Of these one of the most remarkable is Mnium hygrometricum. If the fruit-ſtalk be moistened at the bottom, the head makes three or four turns; and if the head be moistened, it turns the contrary way. By some authors this is ranged with the Bryums; and Hedwig makes it a *Leptostoma.* In Schreber's edition of Linnæus's genera, this genus wholly disappears, being immerged in those of Bryum, Cynaphis, Dicranum, Tortula, Fumaria, Meesia, &c.

DESCRIPTION, *&c.*

This is an annual plant, with a very slender root. Stem filiform, eight, ten or twelve inches long, upright, very much branched; covered with linear, very narrow, opposite leaves, dilated at the base, as it were perfoliate, oblong. Flowers axillary, erect, on slender, one-flowered peduncles. Calyx spreading, greenish. Petals narrow, milk white. Stigmas converging. Capsules

ovate-

* Willdenow.

* Linn. suppl.

ovate-conical, yellowish when ripe, containing eight or ten seeds, first white and finally black, kidney-form, shining, fixed by a pedicel to the receptacle [1].

Native of the mountains of France, Italy, Switzerland, Austria, Silesia, among moss on rocks, by the trunks of trees, or springs or little rills of water. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in june and july [2].

MOLDAVICA. See *Dracocephalum*.

Leaves in whorls wedge-form acute, stem subdivided decumbent, peduncles one flowered.

[6. Mollugo triphylla. *Three-leaved Mollugo.*
Linn. cochinch. 62.
Leaves in threes lanceolate, flowers dichotomous.

DESCRIPTIONS, &c.

1. This is an annual herb (as indeed all the rest are) with long diffused smooth alternate branches. Leaves smooth, ending in petioles. Peduncles several, equal, capillary, one-flowered from the axils.

Native of Ceylon [3].

2. Root fibrous. Stems three or four, stiff, even. Leaves in whorls, frequently in fours, stiff, acuminate, even. Panicles, longer than the leaves, the first and second divisions forked, then racemed. Flowers nodding, white, very much resembling those of M. verticillata [4].

The stem is sometimes diffused with upright branches, sometimes upright, always angular, smooth, dichotomous. Branches divaricating, and like the stem. Leaves in fours, unequal, two being commonly larger, sessile, attenuated below, lanceolate, entire, smooth. Panicle axillary, first dichotomous, then branched, divaricating. Peduncles and pedicels capillary [5].

Native of Africa, Ceylon, Japan.

3. Native of the Cape of Good Hope [6].

4. Root-leaves oblong, narrowed at the base, blunt at the end. Stems decumbent, branching immediately from the ground, with four or five leaflets at each ramification, one-third only of the size of the others. From the axils of these spring very long peduncles, having the flowers collected at top in an umbel (or rather panicle.) They are white, and are succeeded by a very thin, smooth, membranaceous capsule, containing very small blackish seeds.

Native of Ceylon [7]. The other Aline figured by Burman in the lower part of the same plate seems to be only a larger variety of this.]

5. This is a trailing plant, spreading out eight or nine inches every way, and having six or seven small leaves at each joint, spreading out in form of a star. Flowers small, like those of Chickweed, one on each footstalk; succeeded by oval capsules, filled with small seeds.

[Browne remarks, that the leaves and branches are very small; that the stalk seldom runs above six or eight inches from the root; that the flowers are generally four or five together, and grow in single tufts on the sides of the whorls.

Capsule ovate, rounded-three-cornered, thin, pustuled with the protuberant seeds, and at the same time elegantly scored with arched streaks in the pustules themselves. Partitions inserted in the middle of the valves. Seeds about twelve in each cell, subglobular, beaked, marked on the back with three acute prominent lines, very smooth, shining, ferruginous or deep chestnut, fastened to the central angle of the cells by umbilical chords [8].

Native of Virginia and Jamaica, where it is pretty common in the dry savannas of Liguanee. Cultivated by Mr. Miller, in 1759 [9].

6. Stem herbaceous, annual, diffused, four-cornered, half a foot high, with ternate branches. Leaves stellate-tern, smooth, quite entire, sessile. Flowers apetalous lateral and terminating, on long dichotomous peduncles, racemed at top. Stigmas three sessile subovate unequal. Capsule ovate, three-lobed, containing many kidney-form seeds.

Native of China near Canton [10].]

PROPAGATION AND CULTURE.

If the seeds be permitted to scatter, the plants will sometimes come up the following spring; but if they are sown on a hot-bed, they will come up more certainly and the plants will be forwarder and stronger.

Calyxes funnel-form five-cleft, corollas longer than the calyx.]

DESCRIPTIONS, *&c.*

1. Root annual. Stem three feet high, fpreading out into many branches, which are fmooth, and come out by pairs. Leaves roundifh, deeply notched on their edges, oppofite, on long petioles, fmooth, light green on both fides. At the bafe of the petioles the flowers come out in whorls. Immediately under the calyx come out two bunches of pretty long fpines, one on each fide, each bunch conſiſting of five or ſix ſpines ariſing from the ſame point. Corolla ſmall, and being placed at the bottom of the large calyx is not viſible at a diſtance: it is white with a caſt of purple.

[The four ſeeds lie within the calyx, which is unchanged: they are ſtiort, thick, three-ſided, ſmooth, bay-coloured [a]. — Native of Syria. Cultivated in 1570, by Matthias de L'Obel. It flowers in july and auguſt [b].

2. Root annual. Stems ſmooth, purpliſh, four feet high, branching out in the ſame manner with the firſt. Leaves ſmaller, on ſhorter foot-ſtalks, deeper and more acutely indented on their edges. Calyx not ſo large, and cut into eight ſegments, each terminated by an acute ſpine. Flowers and ſeeds like thoſe of the preceding.

[Whorls ſix-flowered, ſeſſile. Involucre with four ternate linear ſpreading thorny ſpines. Upper lip of the calyx larger, acuminate-thorny: lower rounded, entire, with ſeven ſpines. Corolla longer than the calyx; whereas in the preceding the calyx is much longer than the corolla [c].

Native of the Levant. Cultivated in 1739, by Mr. Miller. It flowers in july and auguſt [b]. Commonly ſaid to be a native of the Molucca iſlands.

3. This is a ſmall ſhrub with dichotomous branchlets. Leaves ovate, an inch long, pubeſcent with hairs thinly ſet, having two or three deep ſerratures on each ſide, petioled. Spines axillary, ſolitary on each ſide, ternate as in the Barberry, but only at the whorls of flowers. Calyxes funnel-form, ſmall, ten-cornered, regular with a five-cleft border, and ten terminating ſpines. Corolla like that of Cardiaca, twice as long as the calyx, with a woolly helmet. It ſeems to form the link between Ballota Leonurus and Molucella [d].

Allione thus deſcribes the Italian plant. It is a ſmall ſhrub, very much branched dichotomouſly; the ſtems and branches round, ſtriated and woody: the whole branches are covered with flowers, of which there are from two to ſix in each whorl. There are four ſpines at the origin of the leaves, two on each ſide. Leaves on ſhort petioles, oval, either entire, or with three or five blunt teeth; they are nerved, veined, and have ſhort hairs on them. Calyxes ten-ſtreaked, tubular, ſmooth, with a five-cleft ſpreading mouth: the larger ſtreaks divide the ſegments of the calyx, the intermediate ſmaller ones reach as far as the interſtices of the ſegments of the calyx. The larger ſtreaks always end in ſpines. Tube of the corolla almoſt equal to the tube of the calyx: helmet a little arched, and covered with a long thick pile: middle ſegment of the beard cordate-ſquare, emarginate, and ſlightly bent back on each ſide. Anthers dulky-purple. Seeds oblong, acuminate, not rough.

Native of Perſia, whence it has migrated into Italy. Obſerved by Sherard between Tende and Braille in Piedmont.

In the Perſian plant the leaves are more pubeſcent, with ſharper ſerratures. The ſegments of the calyx are obovate, membranaceous, ſharpen, and have about three teeth. It is however certainly the ſame plant.]

PROPAGATION AND CULTURE.

The two firſt are annual plants, which decay ſoon after the ſeeds are ripe, and being natives of warm countries, ſeldom perfect their ſeeds in England, when they are ſown in the ſpring. They ſhould be raiſed therefore in autumn, and planted in ſmall pots, placed under a hot-bed frame in winter, where they may have free air in mild weather, by taking off the glaſſes; but they muſt be covered in froſty weather, obſerving to keep them pretty dry, otherwiſe they are very ſubject to rot. In the ſpring the plants may be turned out of the pots, with all the earth about their roots, and planted in a warm border, defended from ſtrong winds, giving them a little water to ſettle the earth to their roots; after this, they will require no other care but to keep them clean from weeds, and to ſupport them with ſtakes to prevent their being broken by the winds. The plants thus preſerved through the winter, will flower at the end of june, and good ſeeds may be expected from them.

DESCRIPTIONS, &c.

[Peduncles one-flowered or many-flowered. Momordica of Tournefort has the fruit warted, burſting open at the ſide; ſeeds arilled, engraved on the ſurface, and irregular at the edge. Luffa of Tournefort has the fruit ſmooth, burſting at top, netted-ſpongy within with pulp that ſoon diſappears; ſeeds entire at the edge and not arilled. Elaterium of Tournefort has the fruit ſmaller, rough, burſting from the peduncle with a ſpring, and at the ſame time emitting the ſeeds through the hole. This ſpecies alſo does not climb or creep, and has no tendrils[a]. They are all annual plants, except the laſt.]

1. Stems trailing, like thoſe of the Cucumber and Melon, extending three or four feet in length, and ſending out many ſide branches, which have tendrils. Leaves ſhaped like thoſe of the vine, ſmooth, deeply cut into ſeveral ſegments, and ſpreading open like the hand.

[The fruit, which is called a Pome by Linnæus, a Berry by Gærtner, is fleſhy, ovate, drawn to a point at each end, obſcurely angular, remotely tubercled in longitudinal rows, ſmooth in the other parts, red when ripe, one-celled, inflated, burſting irregularly, and diſperſing the ſeeds with a ſpring. Seeds fixed to the inſide of the fruit in three longitudinal rows, and in ſuch a manner that the umbilicus alternately points to the right and left of the ſame row; they are ovate, flatted a little, horizontal, bluntly notched at the edge and marked with riſing ſerpentine lines, but on the diſk rugged with raiſed dots, their colour is pale brown, and they are covered with a membranaceous, thin, red aril[b].

Native of India. Cultivated here in 1568, as appears from Turner's herbal. It flowers in june and july[c].

This plant is famous in Syria for curing wounds. They cut open the unripe fruit, and infuſe it in ſweet oil, expoſed to the ſun for ſome days, until the oil is become red. It is applied to a freſh wound dropped on cotton. The Syrians eſteem this next to Balſam of Mecca. The leaves and ſtems are alſo uſed for arbours or bowers[d].

2. Stem round, ſlender, branched, climbing by lateral tendrils. Leaves ſinuate-palmate, wrinkled, ſmooth, toothed, ſpread out into a ring, having the nerves pubeſcent; they are alternate and petioled. Flowers ſometimes hermaphrodite, on long, axillary, one-flowered peduncles. Corolla yellow, uſually five-parted, but ſometimes ſix-parted. Stamens three, connected. Fruit oblong, bluntly angular, tubercled, drawn to a point at each end, white yellow or green on the outſide, within very red and fleſhy, one-celled; it burſts elaſtically. Seeds ovate, flat, bitten at the edge[e].

Linnæus obſerves, that the cordate embracing involucre marks a great affinity between this and the preceding; but in this it is quite entire, in that toothed.]

Mr. Miller, following Tournefort, makes two ſpecies of this, with a longer and with a ſhorter fruit. The firſt (n. 2.) has the leaves extended more in length, and hairy; the fruit is much longer than that of M. Balſamina, and not ſo deeply channelled; the tubercles are ſcattered all over the ſurface, and are not ſharp; the colour when ripe is yellow.

The ſecond, which he names M. Zeylanica, has the fruit ſhort and pointed, like that of M. Balſamina, but does not ſwell ſo large in the middle, the angles are not deep, and the whole ſurface is cloſely ſet with ſharp tubercles, when ripe it is of a deep orange colour.

[Native of the Eaſt Indies. Cultivated in 1731, by Mr. Miller. It flowers in june and july[f].

3. Fruit green, the top falling off when it is ripe, like a lid; within it has no pulp, but is dry, and filled with netted fibres, very much interwoven, and is three-celled. Seeds compreſſed, black.

Native of America[g].

4. Stem angular, very much branched, climbing by biſid ſpiral tendrils. Leaves having five or ſeven ſharp angles, the middle one double the length of the others, unequally ſerrate, veined, wrinkled, on long alternate petioles. Male flowers ſeveral together, terminating; corolla ſix-parted, wrinkled, ſpreading. Females lateral, ſolitary; corolla five-parted, reflex. Pome a foot long, two inches thick, roundiſh, uſually drawn to a point at each end, hairy, three-celled,

[a] Juſſieu. [b] Gærtner. [c] Hort. kew. [d] Haſſelquiſt. [e] Loureiro. [f] Hort. kew. [g] Linn.

with

with a white, flaccid, esculent pulp, of an insipid flavour. Seeds oblong, compressed, smooth [a].

Linnæus remarks, that the seeds are whitish; the flowers polyadelphous, five-stamened; the tendrils as it were umbelled at top with several smaller tendrils.

The Arabians call this plant Liff or Luff; they cultivate it, and it climbs up the Palm trees, covering and elegantly adorning their trunks [b]. It is also cultivated largely in China and Cochinchina, &c.]

The fruit, when young, is made into a pickle, like the Mango, but it has a disagreeable taste, and is not accounted very wholesome. Mr. Miller, following Tournefort, has made it a distinct genus from Momordica, but does not separate this species from the next succeeding.

[Native of the East Indies. Cultivated in 1739 by Mr. Miller. It flowers in july and auguſt [c].

5. Stem five-angled. Leaves like those of the Cucumber, serrate-toothed at the base, the middle angle more lengthened, the sinuses not widened as in the preceding, but with straight angles. Pomes a foot long, subvillose, cylindric. Seeds black. Tendrils from the axils [d].

Stem climbing by tendrils, long, branched. Leaves cordate, nine-angled, with the angles intrant rounded, toothletted, rugged. Flowers on long many-flowered peduncles. Pomes two feet long and more, straight, pendulous, blunt, netted-wrinkled, eatable but insipid. Anthers in the male flowers linear, creeping, three separate. Seeds compressed, oblong, smooth, black.

This and the preceding species have not elastic fruit, nor are they capable of opening with a spring, for they consist, as Rumphius observed, of very tough intricate fibres that can hardly be torn asunder. The two first species have none of these fibres, but either burst or rot whole, without in either case leaving any fibres [e].

Native of Ceylon and China.

6. Native of the East Indies.

7. Native of Peru [f].

8. This has a large fleshy perennial root, somewhat like that of Bryony. Stems thick, rough, trailing, dividing into many branches, and extending every way two or three feet. Leaves thick, rough, almost heart-shaped, gray, on long foot-stalks. Flowers axillary, much less than those of the common Cucumber, of a pale yellow colour, with a greenish bottom: the male flowers stand on short thick peduncles; but the female flowers sit on the top of the young fruit, which grows to an inch and half in length, swelling like a Cucumber, of a gray colour like the leaves, and covered with short prickles. The fruit does not change its colour, but when ripe quits the peduncle, and casts out the seeds and juice with great violence: so that the seeds are scattered round to a considerable distance, and plenty of plants will come up the following spring.

But when this fruit is designed for medicinal use, it should be gathered before it is ripe, otherwise the greatest part of the juice, which is the only valuable part, will be lost; for the expressed juice is not to be compared with that which runs out of itself; and the Elaterium made from the clear juice is whiter and will keep much longer than that which is extracted by pressure.

[All parts of the plant are bitter and strongly purgative; but the dried juice or faeculæ of the fruit, known in the shops by the name of Elaterium, is the only part now medicinally employed. The method directed in the London Pharmacopœia for preparing this medicine is: to slit the ripe fruit, and pass the juice (very lightly pressed) through a very fine sieve into a glass vessel; then to set it by for some hours, until the thicker part has subsided; to pour off the thinner part swimming at the top, and separate the rest by filtering; to cover the thicker part which remains after filtration with a linnen cloth, and to dry it with a gentle heat.

The sensible qualities of this inspissated juice are not remarkable either to the smell or taste: it is inflammable, and dissolves readily in watery or spirituous menstrua. Elaterium is a very powerful cathartic, and was frequently employed as such, both by the Greek and Arabian physicians; and its use has since been much commended in hydropic cases, particularly by Pauli, Sydenham and Lister. It is undoubtedly the most violent purgative in the Materia Medica, and ought therefore to be administered with great caution, and only where milder cathartics have proved ineffectual. The dose is from half a grain to three grains: the most prudent and effectual way in which dropsies are now treated by this remedy, is by repeating it at short intervals in small doses [g].

Native of the South of Europe. Cultivated by Gerarde in 1596. Called in English, Wild, Spirting, Squirting, or Asses Cucumber. In French, Concombre sauvage ou d'ane.]

PROPAGATION AND CULTURE.

1 to 7. Sow the seeds on a hot-bed the beginning of march; and when the plants come up prick them into a fresh hot-bed, letting them have fresh air in warm weather, and refreshing them frequently with water. When the plants have four or five leaves, plant them out into the hot-bed where they are to remain, putting one or two plants into each light; watering and shading them until they have taken root. After this, treat them as Melons or Cucumbers, permitting their branches to extend in the same manner, and keeping them clean from weeds. With this management, if they have not too much wet, and are not too much exposed to the open air, they will produce fruit in july, and the seeds will ripen in auguſt and ſeptember: when it muſt be gathered as ſoon as it opens, otherwiſe the ſeeds will be caſt abroad, and with difficulty gathered up again.

When the plants ſpread ſo as to fill the frames, they may be raiſed on bricks, and the ends of the plants drawn out; for when theſe are vigorous, they will ſpread eight or ten feet, and if they are confined will become ſo thick, that the tender branches will rot, and no fruit will be produced.

Theſe plants may alſo be ſet in pots, placed in the ſtove, and the vines faſtened to ſtakes. And thus, when they are ſkilfully managed, they will produce their fruit tolerably well; and in this way they make a better appearance, than when the Vines ſpread on the ground like Cucumbers and Melons. But when the plants ſpread on the ground, which is their natural way of growing, they thrive much better, and produce more fruit, than when they are ſupported; for though theſe plants have claſpers, yet theſe are not formed for climbing, but merely to faſten themſelves about any neighbouring ſupport, to ſecure them from being raiſed by the wind and broken; which would often happen, where they grow in the open air and are fully expoſed, were it not for this ſecurity.

The eighth ſort is eaſily propagated by ſeeds, which if permitted to ſcatter, will come up the following ſpring; or if the ſeeds are ſown upon a bed of light earth, the plants will come up in about a month after, and may be tranſplanted to an open ſpot of ground, in rows at three or four feet diſtance, and almoſt as far aſunder in the rows; if theſe are carefully tranſplanted while young, there will be little hazard of their growing; and after they have taken new root, they will require no farther care, but to keep them clear from weeds. If the ground is dry in which they are planted, the roots will continue three or four years, unleſs the winter ſhould prove very ſevere.

MONARDA. (*So named from Nic. Monardes a Spaniſh phyſician of Seville in the ſixteenth century.*)

DESCRIPTIONS, &c.

1. Root perennial, compoſed of many ſtrong fibres, and ſpreading far on every ſide. Stems near three feet high, are hairy and obtuſe-angled; they ſend out two or four ſmall ſide branches towards the top. Leaves oblong, broad at the baſe but terminating in acute points, hairy, a little indented on their edges, on ſhort hairy foot-ſtalks. Stem and branches terminating by heads of purple flowers, which have a long involucre, compoſed of five acute-pointed leaves. [Seeds ſmall, ſubovate, turgidly lenticular, ruſeſcent, with two very ſmall umbilical excavations, lying within the calyx, which is cloſed at the mouth with hairs converging into five ſcalelets[a].

Native of Canada. Cultivated in 1656, by Mr. John Tradeſcant, jun. It flowers from june to auguſt[b].

2. This differs from the preceding in having the leaves ovate at the baſe and a little attenuated, and more villoſe underneath; the calyxes ſhorter and more villoſe at the edge, and the corollas ſmaller[c].

Native of North America. Cultivated in 1761, by Mr. James Gordon. It flowers from july to ſeptember[d].]

3. Root perennial. Stems about two feet high, ſmooth, acute-angled. Leaves indented on the edges, on very ſhort foot-ſtalks; when bruiſed they emit a very grateful refreſhing odour. Towards the top of the plant come out two or four ſmall ſide branches, with ſmaller leaves of the ſame ſhape. The flowers are produced in large heads or whorls at the top of the ſtalk, and there is often a ſmaller whorl at a joint below the head; and out of the head ariſes a naked peduncle, ſuſtaining a ſmall head or whorl. The flowers are of a bright red colour; many of them have two ſhorter ſtamens without anthers, beſides the two longer fertile ones. They come out in july, and in a moiſt ſeaſon, or when the plants grow in a moiſt ſoil, they continue till the middle or end of ſeptember.

[Linnæus remarks, that the upper leaves are caneſcent.—Native of North America. Introduced in 1755, by Peter Collinſon, Eſq.[e]

4. This reſembles the next following ſpecies, but the leaves are longer, ſmooth, wrinkled a little like thoſe of ſage, and the flowers white[f].—Native of North America. Cultivated in 1761, by Mr. James Gordon. It flowers from july to ſeptember[g].

5. Root creeping. It has the appearance of the third ſort as to its ſtature, but has the leaves of Clinopodium incanum; nor is the ſpike red, but purple, nor have the flowers four ſtamens. It is diſtinct from the firſt by the great ſmoothneſs of the leaves; which are ovate-oblong, acuminate, deeply ſerrate, petioled, ſmooth and even on both ſides. Stem more ſharply quadrangular than the firſt, but leſs ſo than the third. Flowers in a head radiated with bractes, pale.—Native of Virginia[h].]

6. Stems about two feet high, branching out from the bottom to the top. Leaves lanceolate, coming out in cluſters at each joint, where there are two larger leaves, and ſeveral ſmaller ones on each ſide: the larger leaves are two inches and a half long, three quarters of an inch broad, and ſlightly indented on their edges. Towards the upper part of the ſtem the flowers come out in large whorls, with an involucre to each whorl compoſed of ten or twelve ſmall lanceolate leaves, of a purpliſh red colour on their upper ſide: [four larger, and four ſmaller, beſides the leaves of the whorls:] the flowers are pretty large, of a dirty yellow colour ſpotted with purple. It is a biennial plant, and probably in North America, its native country, it may be annual, for the roots periſh here, after the plants have perfected their ſeeds.

[It is a native of Maryland and Virginia, and flowers here from june to october. Mr. Thomas Fairchild cultivated it in 1714[i].

7. Root creeping. Stem hairy, thickiſh, a foot high and more, with few joints; from the lower of theſe the leaves are roundiſh, an inch long, notched, petioled; from the two upper ones the leaves are long and narrower, crenate, ſeſſile. The three or four upper joints have large whorls of flowers, with about ten ſhort, broadiſh leaflets under them. Flowers large, blue, elegantly marked with dark purple ſpots. Found in Virginia by Baniſter[k].]

PROPAGATION AND CULTURE.

1 to 5. Theſe ſorts may be propagated by parting their roots; the firſt does not multiply ſo faſt as the third, but as that produces plenty of ſeeds, ſo it may be eaſily propagated that way. If the ſeeds are ſown in the autumn ſoon after they are ripe, the plants will come up the following ſpring; but if they are not ſown till ſpring, the plants ſeldom riſe till the next year. When the plants are come up and are fit to remove, they ſhould be tranſplanted into a ſhady border about nine inches diſtance, and when they have taken new root, they will require no other care but to keep them

[a] Gaertner. [b] Hort. kew. [c] Willdenow. [d] Hort. kew. [e] Ibid. [f] Willdenow. [g] Hort. kew. [h] Linn. [i] Hort. kew. [k] Moriſon.

clean from weeds till the autumn, when they ſhould be tranſplanted into the borders where they are to remain. The following ſummer they will flower and produce ripe ſeeds, but the roots will continue ſeveral years, and may be parted every other year to increaſe them. This loves a ſoft loamy ſoil, and a ſituation not too much expoſed to the ſun.

The third ſort ſeldom ripens ſeeds in England, but it increaſes faſt enough by its creeping roots, as alſo by ſlips or cuttings, which, if planted in a ſhady border in May, will take root in the ſame manner as Mint or Balm; but as the roots multiply ſo faſt, there is ſeldom occaſion to uſe any other method to propagate them.

This ſort loves a moiſt light ſoil, and in a ſituation where the plants have only the morning ſun, they will continue longer in flower than thoſe which are expoſed to the full ſun. This is a very ornamental plant in gardens, and the ſcent of the leaves is very refreſhing and agreeable to moſt people, and ſome are very fond of the tea made with the young leaves.

6. This is propagated by ſeeds, ſown on a border of light earth expoſed to the eaſt. When the plants are fit to remove, they may be tranſplanted into a ſhady border; and if they ſhould ſhoot up ſtalks to flower, they ſhould be cut down to ſtrengthen the roots, that they may put out lateral buds, for when they are permitted to flower the firſt year, the roots ſeldom live through the winter. In autumn the plants may be removed into the open borders of the pleaſure garden, where they will flower the following ſummer, and if the ſeaſon ſhould prove dry they ſhould be duly watered.

DESCRIPTION, *&c.*

This is a middle-ſized, prickly ſhrub, with the habit of Barleria Hyſtrix. Stem upright, full of chinks, aſh-coloured. Branches oppoſite, diffuſed, denſe, aſh-coloured. Branchlets prickly, bent down, four-cornered, green at firſt, afterwards aſh-coloured. Shoots green, pubeſcent in their natural ſoil, but in gardens naked. Prickles four, in whorls, decuſſated, horizontal, axillary, a pair from each axil, awl-ſhaped, pungent, green, mortified at top, having one ſtreak on the inner ſide, the length of half the leaf. Leaves oppoſite, ſpreading, ovate or ovate-lanceolate, entire, acuminate; the point thorny, ſharp, mortified, reflex; they have one nerve, ſcarcely prominent underneath, with few, hardly viſible veins, of the ſame colour on both ſides, either flat or converging a little on the ſides, permanent, an inch and half long and eight lines wide. Petiole very ſhort, obliquely twiſted, gibbous on one ſide, flat on the other. Flowers axillary on the ſhoots, few, in cluſters, in threes at the top, ſometimes ſolitary, ſeſſile, herbaceous, two lines wide. Bractes two-leaved, oppoſite, preſſed to the flowers laterally, very narrow, acute, changing into prickles[a].

Native of the Eaſt Indies and the Cape of Good Hope. Cultivated in 1758, by Mr. Miller. It flowers in july[a].

DESCRIPTIONS, &c.

1. Root compoſed of imbricate ſcales, and paraſitical, the radical fibres adhering to the roots of the trees under which it grows. Stem from five to ſeven inches high, upright, not branched, ſmooth and ſhining, round, having no leaves, but only ovate, blunt, alternate ſcales, yelloviſh white when young, but ruſty black in the maturity of the plant, terminated by a looſe ſpike of flowers that nods, but in the ſeeding ſtate becomes erect. Flowers pedunculed, each ſupported by its whitiſh ſcaleſet or bracte; they are eight lines in length, and four in diameter. Calyx or outer petals ſmooth, whitiſh and ſhining, very ſlightly ciliated at the edge. Corolla or inner petals of the ſame colour. Pollich reckoned about nine flowers in a raceme. Linnæus remarks, that the whole plant ſmells ſweet, and is of a pale yellow colour, which peculiarity is generally confined to paraſitical plants, and ſuch as grow in very ſhady ſituations. The ſmell is deſcribed as being like that of Primroſe or Beans in bloſſom*.

Willich obſerves that the number of parts varies too much in this plant, to admit of the rule which Linnæus lays down reſpecting it being general. In a ſpecimen which he had before him the terminating flower, beſides the four ſcales under it, had twelve petals, as many ſtamens, a ſtigma with five lines, and a five-celled fruit: but the lateral flowers had four, ſix, ſeven, eight, ten petals, ſix, eight, nine, ten, eleven, twelve ſtamens, four and five lines on the ſtigma, and the fruit four or five-celled.

This plant is nearly allied to Orobanche in its habit and appearance, but the ſtructure of the flowers is different†.

In Sweden it is given dry to ſheep that are affected with a cough*.

Native of many parts of Europe, as Sweden, Denmark, Germany, France, Italy, Britain, alſo in Canada; in woods, eſpecially fir woods, and where the ground is covered with rotten leaves, at the roots of fir, pine, beech, oak, &c. With us in Oxfordſhire, in Stokenchurch woods and between Nettlebed and Henley, Bedfordſhire, Buckinghamſhire, Berkſhire, frequent; Maidſtone in Kent; Tring in Hertfordſhire; in the beech woods of Suſſex; in Selborne-hanger, Hampſhire; Uley in Glocesterſhire; Enville, in Staffordſhire; Shottiſham and Stoke in Norfolk. In Scotland, but not common.

2. Stem ſingle, fleſhy, the ſize of a ſtraw, a long ſpan in height. Leaves broadiſh, pointed, ſattiſh. Flower one, terminating, an inch in diameter, compoſed of five petals, a quarter of an inch wide. Capſule turgid, oblong, ending in a point, the ſize of a hazel nut‡.

Native of North America: whence it was ſent by Banſter. Moriſon's figure is bad, and Catesby's good.

Claſſ. 16. 5. Monadelphia Dodecandria.
Nat. order of *Geuinales. Gerania*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* lanceolate, awned, equal, permanent.
COR. *Petals* five, obovate, præmorſe-toothed, longer than the calyx, inſerted into the baſe of the pitcher of ſtamens.
STAM. *Filaments* fifteen, united in five bodies, three in each, all connected at the baſe and forming a very ſhort pitcher. *Anthers* oblong.
PIST. *Germ* five-cornered, ſhort. *Style* awl-ſhaped. *Stigmas* five, oblong.
PER. *Capſule* five-cornered, five-celled: each cell fixed to a very long, twiſted, terminating tail.
SEEDS ſolitary.

OBS. *Allied to Geranium.*

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* five-petalled. *Stam.* fifteen, united into five filaments. *Style* five-cleft. *Capſ.* five-grained.

SPECIES.

1. Monſonia ſpecioſa. *Fine-leaved Monſonia.*

Geranium folio tenuiſſime diſſecto, flore ſingulari ampliſſimo. *Breyn. prodr.* 3. *app.* 31. *t.* 21. *f.* 2.
Leaves quinate, leaflets bipinnate.

2. Monſonia lobata. *Broad-leaved Monſonia.*
Lin. ſyſt. 697. *Montin in act. gothob.* 2. *p.* 1. *t.* 8. *Ait. hort. kew.* 3. 100. *Curt. magaz.* 385.
M. filia. *Lin. ſyſt.* 696. *ſuppl.* 341. *Cavan. diſſ.* 3. 180. *t.* 74. *f.* 2.
Leaves cordate lobed toothed.

3. Monſonia ovata. *Undulated Monſonia.*
Cavan. diſſ. 4. 193. *t.* 113. *f.* 1. *Ait. hort. kew.* 3. 100.
Leaves oblong, ſubcordate, crenate, waved.

DESCRIPTIONS, &c.

1. Leaves radical, petioled, ſeveral, bipinnate-quinate: leaflets linear, pinnate: pinnas ſublanceolate. Scapes two or three, one-flowered, a ſpan high, twice as long as the leaves, having in the middle a ſmall ſix-leaved involucre, with lanceolate leaflets. Flower handſome. In habit and fructification it bears great affinity to Geranium, but is diſtinguiſhed from it by its appearance like Anemone, and by the difference in the ſtamens and ſtyle‡.

2. According to the younger Linnæus, this is very like the preceding, differing in no reſpect from it in the ſcape, involucre, calyx, petals, ſtamens, piſtil, and even the very ſingular crown of the germ. But the leaves are ſimple, bluntly ſeven-lobed, crenate, blunt, ſubpubeſcent, (as indeed the whole herb is) entirely reſembling thoſe of Geranium vitifolium. The fruit has a beak to it, with a very long point, as in Geranium ciconium. Capſule retuſe and as it were crowned§.

Mr. Curtis adds, that it differs from ſpecioſa principally in its foliage, which is undivided; and that the flowers are ſmaller, more handſome in bud than when

* Lightf. Pollich. Krocker. † Villars. ‡ Linn. ſuec.

* Moriſon. † Linn. mant. ‡ Linn. ſuppl.

open, and more frequently produced, but requiring the influence of the ſun to make them expand fully.

Cavanilles ſeems to think it perfectly diſtinct from the preceding.

3. The ſtem of this ſpecies is herbaceous, columnar and filiform: the leaves oppoſite, about equal in length to the footſtalks, ovate, crenated, about half an inch long, with ſome hairs: the ſtipules are two on each ſide, ſubulate: flowers axillary, on very long footſtalks; about the middle of the length of the footſtalk are two ſtipules: the footſtalk of the flowers is upright: when bearing the fruit it is declinate-erect from the ſtipules, one-flowered. Calyx conſiſts of five ovate-oblong, ſharp, awned leaflets. Corolla of five petals with very narrow claws, gradually dilating towards the tip, and there crenate-premorſe, whitiſh-yellow, with three longitudinal ſtreaks. The crown or urceolus of ſtamens ſurrounding the germ is monophyllous, reddiſh, parted into five ſegments, each of which is terminated by three filaments: the anthers are ovate-oblong. The germ is pentagonal, top-ſhaped, villoſe: ſtyle ſimple; ſtigmas five. Fruit five capſules, monoſpermous, oblong, acute at their baſe, and terminated by a tortile awn of about an inch and half in length[1].

They are all natives of the Cape of Good Hope, and were introduced here in 1774, by Mr. Francis Maſſon. The two firſt are perennial, and flower in april and may. The third is biennial and flowers in auguſt[2].

PROPAGATION AND CULTURE.

1. This plant rarely or never ripening its ſeeds with us, may be increaſed by cuttings of the root planted in pots of good mould, and plunged in a tan-pit, watering them occaſionally: in due time buds appear on the tops of the cuttings left out of the ground. It may be treated as a hardy greenhouſe plant, and may be ſheltered even under a frame in winter[3].

The ſecond ſort may be raiſed in the ſame way, and the third from ſeeds.

DESCRIPTION, *&c.*

Root annual, fibrous. Stalks numerous, round, ſmooth, ſucculent, reddiſh, ſpreading on the ground, and ſometimes ſtriking root, two or three inches in length, branched and jointed. Leaves oppoſite, ſeſſile, oblong, ſomewhat pointed, narrowed near the baſe, rather fleſhy, ſmooth and of a pale green colour. Peduncles generally growing three together, each ſupporting one flower, proceeding from a little ſcale in the boſom of the leaves, as ſoon as the flowering is over hanging down, afterwards becoming upright and longer than the leaves. Corolla white. Filaments ſhorter than the corolla to which they are connected. Germ large at top, ſmall at bottom, and ſomewhat triangular. The permanent and encreaſing calyx, truncated at top inveſts the capſule[4], which is ſubglobular, and contains three ſeeds, which are turgidly lenticular or ſubglobular, beaked, rugged with very cloſe tubercles, black, fixed by a very ſhort umbilical chord to the bottom of the capſule[5].

The flowers uſually appear in a half-opened ſtate, whence one of the Engliſh names *Blinks*, but when the ſun ſhines on them they expand[6]. Stamens three or five. Capſules ſubtriquetrous, the valves burſting elaſtically[7].

Cyrillo has figured a raceme of this plant with four or five flowers, which is an unuſual luxuriance.

Allione remarks, that the larger variety grows in bogs, the ſmaller one where water has ſtood in winter; that at firſt ſight they appear to differ, the larger having fewer flowers and on longer peduncles from the axils; in the ſmaller the flowers are rather more abundant on the top of the plant, beſides the axillary ones, the leaves are alſo much ſmaller.

Native of many parts of Europe, flowering in may, and ripening its ſeed at the beginning of june. With us it is not uncommon, as on Blackheath, Hampſtead-heath, Hanging-wood Charlton, about Streatham and Sydenham, Harefield-common, wet heaths in Norfolk, Hill of Health and Gamlingay-heath, Cambridgeſhire, Badby in Northamptonſhire, Bridgeford in Nottinghamſhire, Hockley Pool Grate near Birmingham, Shotover-hill and South Leigh-heath in Oxfordſhire, Marazion-marſh in Cornwall.]

M. fruticosa. *Gærtn. fruct.* 1. 170.

DESCRIPTION, &c.

Root woody. Stem shrubby, angular, branched, smooth, a foot high. Branches alternate, little divided, glaucous, scarred with the residue of the petioles. Leaves alternate, oblong-oval, blunt, nerved, veined, quite entire, smooth, thickish, erect. Petioles very short, subdecurrent, falling off above the base. Flowers terminating, solitary, sometimes but seldom five-cleft, white. Fruit with an acrid flavour[1]. It is an inferior capsule, crowned with the four very spreading toothlets of the calyx, two-valved: partition very thin, contrary to the valves, arising from the receptacle. Seeds in each cell six or eight, rather large, leafy-compressed, concave, slightly emarginate at the navel, with a broad entire membrane about the edge, bay-coloured[1].

Native of the Cape of Good Hope, on sandy hills; found by Sparrman, Thunberg, &c. Introduced here by Masson in 1774.

Moon-Seed. See *Menispermum.*

DESCRIPTION, *&c.*

[Linnæus remarks that the flower of Moræa differs from that of Iris, in having all the ſix petals equally ſpreading. This being the chief difference, Gærtner is of opinion that Moræa is too artificial a genus, and might more properly be mixed partly with Iris and partly with Ixia. Moræa, according to Willdenow differs from Siſyrinchium as Ixia does from Galaxia, in having the ſtamens not monadelphous. For this reaſon he refers Moræa ixioides and collina of Thunberg, and ferrariola of Jacquin to the genus Siſyrinchium. But ſeveral of theſe genera border ſo cloſe upon each other, that it is ſometimes not eaſy to determine which of them ſome ſpecies belong to. The Siſyrinchia certainly have the ſame habit and flowers with the Moræas.

1. Petals alternate, the three outer white, the three inner ſmaller and black. Stigma many-parted.—Native of the Cape of Good Hope [a]. Introduced here in 1786, by Mr. Francis Maſſon [b].

2. Corolla equal, greeniſh white on the outſide, white within, rolled ſpirally during the night. Stigma ſimple, villoſe.—Native of the Cape [c].

3. Scape ſimple erect one-flowered or two-flowered. Leaves linear-lanceolate ſubfalcated ſtriated ſmooth, ſhorter than the ſcape. Corolla blue, becoming ſpiral when it is paſt; the alternate ſegments narrower.—Native of the Cape [d].

4. This plant is only an inch or an inch and half high, covered with ſtriated ſheathing leaves. Pedunclé very ſhort one-flowered. Spathe two-valved membranaceous. Corolla white. Stigma trifid. This has been placed in the genus Ixia by Forſter, Galaxia by Cavanilles, and Tapeinia by Juſſieu; but Willdenow has made it a Moræa on account of the corolla being ſix-petalled. Ixia has a tube to the corolla, and Galaxia has cohering filaments.—Native of the Straits of Magellan [e]. See Galaxia.

5. Culms naked long ſmooth and even. Leaves narrow-enſiform very long ſmooth and even, very finely ſtriated. Spikes terminating, uſually three, imbricate, with embracing blunteſh awnleſs glumes. Bractæ enſiform behind the ſpikes, and not longer than them. Corolla yellow, with the outer petals red on the outſide. Styles three.—Native of the Cape [f].

6. Corolla yellow. Stigmas three. This ſpecies is ſingular in being entirely leafleſs, and having the flowers lateral as in Juncus.—Native of the Cape [g].

7. The flowers with their ſpathes reſemble thoſe of Dianthus. Corolla yellow. Stigmas three.—Native of the Cape [h].

8. Leaves and ſtems filiform, the toughеſt and ſmoothеſt of all the ſpecies. Scape terminating in a two-leaved ſpathe, with a head of flowers fenced by ſmaller awl-ſhaped ſpathes. Corolla yellow. Stigmas three [i].

Linnæus formed the character of Bobartia from an imperfect ſpecimen of this plant, as Schumacher has clearly ſhown [k].

It grows very abundantly on the hills near the Cape of Good Hope.

9. Scape ſtriated, upright, ſmooth, a foot high and more. Leaf one (ſeldom two) at the root, linear, ſtriated, ſhorter than the ſcape; branch-leaves ſimilar. Flowers alternate on the flexuoſe rachis of the ſcape. Spathes oblong, acute, jagged. Segments of the corolla ſcarcely connate at the baſe, nearly equal, ovate, blunt with a point, concave, with a raiſed longitudinal line, ſpreading, yellow above, three alternate ones greeniſh underneath. Stigmas ſix or thereabouts, two always approximating, a little longer than the filaments.—Native of the Cape [l].

10. Scape jointed, panicled, upright, a foot high. Branches and branchlets filiform, upright, jointed. Leaf next the root linear, ſtriated, upright, curved, longer than the ſcape: branch-leaves ſimilar. Flowers one, two, or three. Corolla blue, almoſt regular: ſegments ovate, blunt, ſpreading; three alternate a little ſhorter and narrower, with a yellow line below, green on the outſide. Stigmas three, ſcarcely two-lipped, but bifid.—Native of the Cape [m].

11. Scape ſimple, ſtriated, ſmooth, upright, two feet high. Root-leaves very many, diſtich, linear, ſtriated, ſmooth, upright, ſhorter than the ſcape. Flowers lateral, alternate, ſpike-headed, very many. Heads on round pedunclés. General ſpathes boat-ſhaped, acuminate, the length of the head: partial ſpathes ovate, entire, membranaceous at the edge. Corolla blue: ſegments ovate, blunt, concave, veined, from upright ſpreading, ſmooth, alternately ſomewhat narrower. Filaments very ſhort, blue. Anthers oblong, blunt, bifid at the baſe, grooved on the outſide, even within, inſerted laterally, yellow, almoſt the length of the corolla. Germ ſmooth. Style the length of the ſtamens, ſhorter than the corolla, blue. Stigma ſimple, blunt, three-cornered. Capſule oblong, gradually attenuated below, ſmooth.

Native of the Cape [n]. This has been already mentioned, but not deſcribed under Gladiolus.

12. Bulb ovate, covered with red membranaceous coats, yellow in the middle. Leaves radical, from two to three feet long, enſiform, broad, narrower and as it were petioled at the baſe, towards the root membranaceous and ſomewhat ſheathing, purple, longitudinally ſix-nerved, folding over each other, very ſmooth. Scapes rather longer than the leaves, roundiſh or compreſſed a little, ſomewhat ſtriated, ſmooth, nodding a little at top, terminated by a ſpathe-ſhaped lanceolate upright nerved leaflet, from the ſheathing baſe of which iſſues a pedunclé, two inches long, and bifid; each pedicel has a ſmall leaflet under it. Flowers white, ſpathaceous, in a ſort of head, riſing gradually on very ſhort pedicels. Spathe two-leaved, anciptal: leaflets ovate, acute, ſlightly ſtriated, keeled, one of them bifid, ſmooth, including from ſix to ten flowers ſeparated by ovate acute membranaceous pale ſcales. Corolla ſix-petalled. Petals oblong, equal, from upright ſpreading, veined, white, flat with the baſe contiguous to the apex of the germ. Filaments ſhorter than the petals, about the apex of the germ, ſhortly connate. Anthers linear, bifid at bottom. Germ obovate, ſubtrigonal. Style awl-ſhaped, the length of the ſtamens. Stigma three-parted; the parts lanceolate, upright.

Native of the Weſt Indies, as in the mountainous paſtures of Jamaica on the weſt ſide; flowering the whole year, opening at four o'clock in the afternoon, one flower only coming out at a time [o].

13. Scape ſmooth, upright, ſimple, a foot high. Flowers terminating, one, two or three, pedunclé, blue. Involucres two under the umbel, linear, ſtriated, one ſhorter, acuminate, a little longer than the umbel: the other linear, reflex, the length of the ſcape.—Native of the Cape of Good Hope [p].

14. Scape ſimple, a ſpan high. One leaf next the root linear, the length of the ſcape. Flowers terminating, pedunclé, few, blue.—Native of the Cape [q].

15. a. Bulb with the ſcales connected at the ſides, but diſtinct at the baſe: with ten compreſſed teeth, and as many alternately ſhorter. Culm branched; branches three or four. Glumes two-valved, two-flowered. Flowers white [r]. Capſule inferior, ovate, half an inch long, rounded three-cornered, three-grooved, with knobs where the ſeeds are, papery, white, three-celled, three-valved. Seeds fixed to the central margin of the partitions, in a double row, from eight to twelve in each cell, ſubglobular, acuminate towards the umbilicus, ſmooth, of a reddiſh roſt colour [s].

Bulb ſmall, a little compreſſed on the ſides, with a ſmooth dark-coloured ſkin. Leaves three or four, awl-ſhaped, pale green, from five to ſeven or eight inches in length, and about half an inch broad, terminating with three angles. Scapes about ſix inches

[a] Linn. ſuppl. [b] Herb. Linn. [c] Linn. ſuppl. [d] Thunberg. [e] Willdenow. [f] Linn. ſuppl. [g] Ibid. [h] Ibid. [i] Ibid. [k] Willdenow. [l] Thunberg. [m] Thunberg. [n] Ibid. [o] Swartz [p] Thunberg. [q] Ibid. [r] Willdenow. [s] Gærtner.

high,

high, generally bending at the lower joint; with a small leaf at each joint, the base of which almoſt ſurrounds the ſcape. Flowers two terminating, encompaſſed by a withered ſpathe. Corolla orange; the parts pretty broad at top, connected at the baſe.

β. Bulb with ſcales connected at the baſe, biſid, depreſſed, but not compreſſed. Glume two-valved, two-flowered. Flowers two, ſeldom more than two on a ſcape.]

Roots fibrous, like thoſe of the flag-leaved Iris, whence ariſe many ſmall ſword-ſhaped leaves, five or ſix inches long, and half an inch broad in the middle, diminiſhing towards both ends, of a deep green colour, lying over each other at the baſe. Scape about eight inches high, having one ſmall leaf at each joint, and terminated by one flower, covered with a two-valved ſpathe. Corolla dirty white, each part having a bluſh of purple towards the upper part, and a pretty broad ſpot of yellow towards the claw. Stigma trifid.

Natives of the Cape of Good Hope. They flower in June, and the ſeeds ripen at the end of July. It was to theſe that Mr. Miller gave the name of Moræa from Robert More, Eſq. who, as he ſays, was well ſkilled in botany and other parts of natural hiſtory. [He cultivated them in 1758[1].

16. Root fibrous. Scape a ſpan or foot high, roundiſh or ſcarcely compreſſed, jointed, ſmooth, ſimple or little branched, upright, the length of the leaves. Leaves enſiform, narrowed at the inner baſe, nerved, ſmooth, acuminate, upright. Flowers from the uppermoſt axils of the leaves, ſometimes three, but often only one. Spathe two-valved. Germ pedicelled, ſubtrigonal, ſtriated. Corolla ſix-petalled; the three outer petals obovate, oblong, bearded, ſpreading, with a yellow ſpot in the middle: the three inner white without ſpots, ſpreading like the outer ones. Style ſhort, thick. Stigmas petaloid, ſpreading, blue, biſid, as in Iris[2]. Capſule oblong, obſoletely three-cornered, coriaceous, black-brown, very finely ſtriated. Seeds numerous, variouſly angular, depreſſed, with two flat ſides, the others curved with the ſides of the cells; they are thick, black-brown with confluent ſpots[3].

Native of the Cape of Good Hope, according to Miller and the Kew catalogue; but of the Levant, according to Thunberg. Cultivated by Mr. Miller in 1758[4].

17. The ſtyle is inclined. The corolla being ſix-petalled, it is a ſpecies of Moræa; the Ixias having a tube[5]. This has already been ſufficiently deſcribed under Ixia chinenſis. Mr. Curtis thinks that it has ſcarcely any affinity with Moræa.

The corolla in this genus is ſaid to be ſix-petalled in the generic deſcription given above; it is however rather one-petalled and ſix-parted, as in Iris, at leaſt in moſt of the ſpecies; but the connection at the baſe is ſo ſlight, that it is difficult to determine in ſome caſes whether we ſhould conſider the corolla as one-petalled or ſix-petalled. It is the latter in ſpecies 4, 12, 16, 17; in the reſt it is ſubmonopetalous, or ſubhexapetalous.

In the generic character it is ſaid that there are three ſtigmas, or that the ſtigma is trifid. The number three is certainly predominant; but the ſtigma is ſimple in 2 and 11; many-parted in 1 and 15; fexid in 9; in the reſt biſid. Species 5 has three ſtyles.

The corolla is black and white in 1: white in 2, 4, 12, 15, 16; blue in 3, 10, 11, 13, 14: and yellow in 5, 6, 7, 8, 9.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, offſets, or parting the roots; all which operations are beſt performed in autumn. Sow the ſeeds in ſmall pots, plunged into a bed of old tanner's bark, under a common frame. The plants alſo require this ſort of ſhelter in winter, being apt to draw up weak when placed in the dry ſtove. If they can enjoy the free air, even in winter, when the weather is not cold, and are ſecured from froſt and hard rain, they flower and ripen their ſeeds better than with more tender management. In ſummer they ſhould be fully expoſed to the open air till October, when they ſhould be removed into ſhelter.

[Moræa. See *Ariſtea*.

Morogana. See *Zygophyllum*.]

MORINA. (*So named by Tournefort, who diſcovered this plant in his travels in the Levant, in honour of Louis Morin, M. D. member of the academy of ſciences at Paris, who firſt raiſed it from ſeed in his garden at the Abbey of St. Victor.*)

Lin. gen. n. 41. *Reich. n.* 44. *Schreb. n.* 52. *Tournef. t.* 430. *Juſſ.* 194. Diototheca. *Vaill. mem. acad. par.* 1722.

Claſſ. 2. 1. Diandria Monogynia.

Nat. order of *Aggregatæ*. *Diſſaceæ*, Juſſ.

GENERIC CHARACTER.

Cal. double. *Perianth of the fruit* inferior, one-leafed, cylindric, tubular, permanent; *mouth* toothed: *teeth* two oppoſite, longer; all ſubulate, acute.

Perianth of the flower ſuperior, one-leafed, tubular, biſid; *ſegments* emarginate, blunt, permanent, upright, the ſize of the outer.

Cor. one-petalled, two-lipped. *Tube* very long, widening above, a little curved in, filiform at bottom. *Border* flat, blunt: *upper lip* ſemibiſid, ſmaller; *lower* trifid: *ſegments* all blunt, uniform, the middle one more lengthened.

Stam. *Filaments* two, briſtle-ſhaped, approximating to the ſtyle, parallel, ſhorter than the border. *Anthers* erect, cordate, diſtant.

Pist. *Germ* globular, under the receptacle of the flower. *Style* longer than the ſtamens, filiform. *Stigma* headed-peltate, bent in.

Per. none.

Seed ſingle, roundiſh, crowned with the calyx of the flower.

ESSENTIAL CHARACTER.

Cal. of the fruit one-leafed, toothed—of the flower biſid. *Cor.* irregular. *Seed* one, under the calyx of the flower.

SPECIES.

M. orientalis. *Neill. diſſ.*—carlinæ folio. *Tourn. cor.* 48. *it.* 3. 132. *ic.*

DESCRIPTION, *&c.*

Root taper and thick, running deep into the ground, ſending out ſeveral thick ſtrong fibres as large as a finger. Stem near three feet high, ſmooth, purpliſh towards the bottom, but hairy and green at the top. At each joint three or four prickly leaves, like thoſe of Carline Thiſtle, four or five inches long, an inch and half broad, of a livid green on the upper ſide, but of a pale green and a little hairy underneath, armed on theſe edges with ſpines. Flowers axillary on each ſide, ſome white and others purpliſh red on the ſame plant. They appear in July, but do not produce ſeed in England. [Tournefort remarks, that they have the odour of the Honeyſuckle.—Native of Perſia near Iſpahan.]

It was in the Engliſh gardens before the ſevere winter of 1740, which killed all the plants here, and in the Paris garden, ſo that the only plant remaining was in Monſ. Duhamel's garden.

PROPAGATION AND CULTURE.

This plant is propagated by ſeed, which ſhould be ſown ſoon after it is ripe in the autumn, otherwiſe the plants will not come up the following ſummer; for I have ſeveral times obſerved, where the ſeeds have been ſown in the ſpring, they have remained in the ground fourteen or fifteen months before the plants have appeared. Theſe ſeeds ſhould be ſown in the places where the plants are to remain, becauſe they ſend forth tap-roots, which run very deep into the ground; and when theſe are broken or injured in tranſplanting, the plants ſeldom thrive after. They may be ſown in open beds or borders of freſh light earth, being careful to mark the places, that the ground may not

[1] Willdenow. [2] Hort. kew. [3] Linn. mant. & Thunb. diſſ. [4] Gærtner. [5] Hort. kew. [6] Willdenow.

be disturbed; for it frequently happens, that the seeds do not come up the first year, when they are sown in autumn; but when they are sown in the spring, they never come up the same year. The ground where the seeds are sown must be kept clear from weeds, which is all that is necessary to be done, until the plants come up; where they are too close together, they should be thinned while young, so as to leave them near eighteen inches apart; after which time they will require no other culture but to keep them constantly clear from weeds; and in the spring, just before the plants put out new leaves, to dig the ground gently between them, and lay a little fresh earth over the surface of the bed to encourage them.

In autumn these plants decay to the ground, and send forth new leaves the following spring, but it will be three years from the time of the plants first coming up to their flowering, though after that time they will flower every season; and the roots will continue many years, provided they are not disturbed, or killed by very severe frost.

MORINDA. (Morus indica. *Indian Mulberry. So named by Vaillant, from the shape of its fruit, and its country.*)

Lin. gen. n. 235. *Reich. n.* 252. *Schreb. n.* 317. *Vaill. mem. acad. par.* 1722. *Juss.* 209. *Gærtn. t.* 29. Rojoc. *Plum.* 26. Phillyreastrum. *Vaill. mem.* 1722.

Class. 5. 1. Pentandria Monogynia.

Nat. order of *Aggregatæ. Rubiaceæ*, Juss.

GENERIC CHARACTER.

CAL. *Receptacle common* roundish, collecting sessile flowers into a globe.

Perianth five-toothed, scarcely observable, superior.

COR. one-petalled, funnel-form: *tube* cylindric: *border* five-cleft, acute, spreading very much: *segments* lanceolate, flat.

STAM. *Filaments* five, very short, inserted into the tube at top. *Anthers* linear, erect, almost the length of the tube.

PIST. *Germ* inferior. *Style* simple. *Stigma* bifid, thickish.

PER. *Berry* subovate, angular, compressed on all sides by the next, truncate, one-celled.

SEEDS two, convex on one side, flat on the other.

ESSENTIAL CHARACTER.

Flowers aggregate, one-petalled. *Stigma* bifid. *Drupes* aggregate.

DESCRIPTIONS, *&c.*

1. This is a tree, with the leaves of Cephalanthus, opposite, petioled, quite entire. Umbel sessile, or several equal peduncles terminating blunt branches, on each of which sit aggregate heads [a]. Fruit subglobular, on a long peduncle, composed of berries, which are inversely pyramidal, four-cornered, fleshy, one-celled, having no partitions, or such very thin ones that they are obliterated when the fruit is ripe. Seeds four, bony, one-celled, arched on the back, flat on the sides, and towards the axis compressed into a wedge-form edge [b].

Native of the East Indies, Cochinchina, and the Society isles. The root is used for dyeing yellow.

2. Shoots on the upper part quadrangular, grooved and knobbed. Leaves in pairs from the knots, on thick round petioles, large, rounded-oblong, more contracted towards the base, and ending in a point, of a soft thick texture, flat, dark green above, paler underneath: the midrib thick and whitish: the upper leaves gradually smaller, and on shorter petioles. Corolla four or five-cleft, the parts narrow-oblong, pointed, spreading, thick, white within, herbaceous on the outside. Stamens four, five or six, corresponding with the number of divisions in the corolla, short, yellowish [c]. Berry to each flower, conglobated into an ovate-conoid fruit, terminated with slightly depressed mamillæ, and fleshy, marked above with a round eye, somewhat convex, rhomb-wedge-form below, firmly united, four-celled. Seed in each cell one, obovate-oblong, slightly convex on one side, concave on the other, with a subglobular void protuberance on one side below the vertex of the seed. The seeds are fixed, without any receptacle to the base of the cells [d].

Native of the East Indies, and the Society and Friendly islands: where the yellow dye for their cloths is from the bark of the root.

3. Stem shrubby, a foot high, procumbent at bottom, branched. Branches simple. Leaves petioled, lanceolate, entire, smooth; branchlets from the axils of the leaves opposite. Flowers terminating, aggregate in a globular receptacle, white. Calyx tubular, thick, undivided. Tube of the corolla villose within, with a nectariferous base. Style bifid. Stigmas reflex. Berries aggregate, with two seeds to each [e].

The roots dye linen of a dark hue, and would probably be useful to the dyers [f].

Native of South America, and the islands in the West Indies; and also of Cochinchina, according to Loureiro.

Capparis Morisonia. *Swartz obs.* 272.

DESCRIPTION, *&c.*

This is an inelegant upright tree, seldom above fifteen feet in height. Leaves oblong, blunt or acuminate, quite entire, shining, coriaceous, alternate, few, at most a foot long, on a round petiole, thickened at the base and tip, an inch and half long. Short thick peduncles come out scatteringly both on the old and young branches, having commonly four or five flowers on each. These are of a dirty white, have some little smell, and are scarcely an inch in diameter. The segments of the calyx are seldom equal. The stamens are about twenty in number. Fruit brown, with russet-coloured dots: flesh or pulp whitish, not eatable [a]. Gærtner describes it as a superior, spherical, one-celled berry, on a very long pedicel: rind coriaceous, hard, thick, shagreened with dots: flesh fungous, white. Peduncle twice as long as the berry, having callous dots scattered over it, and a swelling, striated joint at the base crowned with a row of very minute tubercles. Seeds numerous, largish, somewhat kidney-form, smooth, whitish or rufescent, immersed in all directions in the pulp.

Native of South America, and the islands of the West Indies; flowering there in july, and bearing fruit in November. In Martinico they call it *Bois Mahouta*, or *Devil's-wood* [b].

Linnæus first placed this tree in the class Polyandria, but afterwards removed it into the class Monadelphia. Swartz is inclined to restore it to its former situation, and even to sink it in the genus Capparis.

DESCRIPTIONS, *&c.*

1. [This is a middle-sized tree, with a whitish bark, of which a coarse sort of paper may be made, and spreading branches. Leaves broad-lanceolate, obliquely cordate, subserrate, undivided, or three-lobed, some cut, smooth, petioled, scattered. Berries lateral, juicy, insipid, pale, oblong [a].

Gærtner describes the fruit as a Capsule covered with the leaflets of the calyx conterminated into a white turbinate berry, ovate-acuminate, membranaceous, full of soft pulp, one-celled, finally drying up into a thin pellicle drawn over the seed. Seed single, (one of the two being constantly abortive,) ovate, drawn to a point upwards, subcuticular, rufescent, fixed to the apex of the capsule by a filiform chord [b].

Native of China, Cochinchina and Japan, and according to Gmelin of Persia. Cultivated by Gerarde, in 1596. It flowers in june [c].]

[a] Loureiro. [b] Gærtner. [c] Hort. kew.

There are two or three varieties of this tree, which differ in the ſhape of their leaves, and in the ſize and colour of the fruit; but as it is of no other uſe but for the leaves, the ſtrongeſt ſhooting and the largeſt leaved ſhould be preferred. [Thunberg ſays it varies with entire leaves, with leaves ſimply lobed, and with the lobes cut or gaſhed.]

The white Mulberry is commonly cultivated for its leaves to feed ſilk-worms in France, Italy, &c. [In Spain, as Mr. Townſend informs us[5], they preſer the White Mulberry in Valencia, and the Black in Granada.] The Perſians generally make uſe of the latter, and Mr. Miller was aſſured by a gentleman who had made trial of both ſorts of leaves, that the worms fed with the Black Mulberry produced much the beſt ſilk; but that the leaves of the black ſhould never be given to the worms after they have eaten for ſome time of the white, leſt they ſhould burſt.

[Sir George Staunton ſays that the trees he obſerved in China did not appear to differ from the common Mulberry-trees of Europe; that ſome of them were ſaid to bear white, and ſome red or black fruit, but that often they bore none; and that the tender leaves growing on young ſhoots of the black Mulberry are ſuppoſed to be the moſt ſucculent[6].

Mr. Evelyn remarks, that the leaves of the White Mulberry are far more tender than thoſe of the Black, and ſooner produced by at leaſt a fortnight. Nor is this tree leſs beautiful to the eye than the faireſt Elm, very proper for walks and avenues. The timber will laſt in water as well as the moſt ſolid Oak, and the bark makes good and tough baſt-ropes[7].

The White Mulberry, and the Silkworm were unknown to Theophraſtus and Pliny. About the year of Chriſt 551 two Perſian monks, employed as miſſionaries in ſome of the Chriſtian churches eſtabliſhed in India, penetrated into the country of the Seres, or China. There they obſerved the labours of the Silkworm, and became acquainted with the art of working up its productions into a variety of elegant fabrics. They explained to the Greek Emperor at Conſtantinople theſe myſteries, hitherto unknown, or very imperfectly underſtood in Europe; and undertook to bring to the capital a ſufficient number of theſe wonderful inſects. This they accompliſhed by conveying the eggs of the ſilkworm in a hollow cane. They were hatched by the heat of a dunghill; they were fed by the leaves of a wild Mulberry-tree, and they multiplied and worked in the ſame manner as in thoſe climates where they firſt became objects of human attention and care. Vaſt numbers of theſe inſects were ſoon reared in different parts of Greece, particularly in the Peloponneſus. Sicily afterwards undertook to breed ſilkworms with equal ſucceſs, and was imitated, from time to time, in ſeveral towns of Italy. In all theſe places extenſive manufactures were eſtabliſhed, with ſilk of domeſtic production.

From the reign of Juſtinian, it was moſtly in Greece, and ſome of the adjecent iſlands, that ſilkworms, which he firſt introduced into Europe, were reared.

Soon after the conqueſt of Conſtantinople by the Venetians in 1204, they attempted the eſtabliſhment of the ſilk manufacture in their dominions; and in a ſhort time the ſilk fabrics of Venice vied with thoſe of Greece and Sicily.

About the beginning of the fourteenth century the Florentine manufactures of ſilk appear to have been very conſiderable[8].

It came much later into France; the manufacture of ſilk, though much encouraged by Henry IV. not having been fully eſtabliſhed there, till under Louis XIV. by Colbert[9]. In England, it is well known, that all the endeavours of James I. to raiſe Mulberry trees, and make ſilk utterly failed, and have never ſince been revived to any extent.

2. The difference which Linnæus ſets down between the Black Mulberry and the White is, that in the former the leaves are ſubquinquelobate, bluniſh, and rugged, in the latter undivided and ſhining; the fructification of the former dioecous, of the latter monoecous. Theſe diſtinctions however are not exact. The Black Mulberry is a larger ſtronger tree; and the fruit is dark blackiſh red and more acid.]

Mr. Miller's account is, that the Black Mulberry has generally male flowers or catkins on the ſame tree with the fruit, but it often happens that ſome of the trees which are raiſed from ſeeds have moſtly male flowers and produce no fruit; and that he has obſerved ſome trees which produced only catkins for many years after they were planted, and afterwards have become fruitful. [This latter obſervation agrees with a general remark that I have made on monoecous trees, that whilſt they are young they bear male flowers chiefly and very little fruit.] Mulberry trees of a certain age are not only more fruitful than young ones, but their fruit is much larger and better flavoured.

This tree grows naturally in Perſia, whence it was firſt brought to the ſouthern parts of Europe. It is now become common in every part of our continent, where the winters are not very ſevere. In the northern parts of Sweden it will not live in the open air; and in ſeveral parts of Germany it is planted againſt walls and treated in the ſame way as Peaches and other tender fruits are here.

It was cultivated here in 1596, by Gerarde.] In ſome of the old kitchen gardens near London there are trees of a very great age, which are very healthy and fruitful, and their fruit is larger and better flavoured than thoſe of younger trees. [Bradley ſays, that moſt of theſe were planted in the time of King James I., when there was a project of ſetting up a ſilk manufacture in England.]

β. Mr. Miller ſets down a variety of the Black Mulberry, with palmate or elegantly cut leaves and a ſmaller fruit, as a diſtinct ſpecies. He ſays, that it grows naturally in Sicily, whence he received a parcel of the ſeeds, and raiſed a good number of plants; that all theſe were totally different in their leaves from the common Mulberry, that the tree is of humbler growth, and the fruit ſmall without any flavour.

γ. This tree makes very ſtrong vigorous ſhoots, but ſeems not to be of tall growth, for it ſends out many lateral branches from the root upwards. The leaves are large, ſome of them entire, others deeply cut into three or five lobes, eſpecially whilſt the trees are young; they are dark green and rough to the touch on the upper ſurface, but pale green and ſomewhat hairy on the under ſide, falling off on the firſt approach of froſt in autumn. The fruit is little larger than peas, ſurrounded with long purple hairs, when ripe changing to a black-purple colour, and full of ſweet juice.

It is a native of Japan and the South Sea iſlands, according to Mr. Miller of China alſo and South Carolina, whence he received the ſeeds. The inhabitants of Japan make paper of the bark. They cultivate the trees for this purpoſe on the mountains much after the ſame manner as Oſiers are cultivated with us, cutting down the young ſhoots in December, after the leaves are fallen.

[Theſe being divided into rods of three feet in length, or ſhorter, are gathered into bundles to be boiled. If the ſhoots are dry, they muſt be ſoftened in water twenty-four hours. The bundles are boiled very cloſe together, and placed erect in a large copper properly cloſed: the boiling is continued till the ſeparation of the bark diſplays the naked wood. Then the ſtalks are looſed out of the bundles, and allowed to cool; after which, by a longitudinal inciſion, the bark is ſtripped off, and dried, the wood being rejected. When this bark is to be purified, it is put three or four hours in water, when being ſufficiently ſoftened, the cuticle, which is of a dark colour, together with the greeniſh ſurface of the inner bark, is pared off. At the ſame time the ſtronger bark is ſeparated from the more tender: the former making the whiteſt and beſt paper; the latter a dark weak and inferior kind. If any bark appears that is old, it is ſet aſide for a thicker paper, of worſe quality. Into this laſt claſs they

[5] Travels, 3. 284. [6] Embaſſy, 2. 430. [7] Syſtem, b. 2. ch. 1.
[8] Robertſon's India, p. 85. from Procopius—alſo p. 110. See Gibbon's hiſtory, IV. 51. under Juſtinian.
[9] Evelyn, b. 2. c. 1.

they throw the knotty parts of the bark, and thoſe which have any fault or blemiſh.

The bark is now boiled in a lye that is clear and ſtrained; care being taken to ſtir the ſubſtance as ſoon as it begins to boil, with a ſtrong reed, and to pour in of the lie gradually as much as is neceſſary for ſtopping the evaporation, and reſtoring the liquor that is loſt.

The boiling is to ceaſe when the materials can be ſplit, by a ſlight touch of the finger, into fibres and down.

Next it is to be waſhed, which is a thing of ſome moment; for if waſhed too ſhort a time, the paper will be ſtrong indeed, but too rough, and of an inferior quality: if too long, it will be whiter, but of a fat conſiſtence, lax, and leſs fit for writing. Being ſufficiently waſhed, the materials are put upon a thick, ſmooth, wooden table, and ſtoutly beat, by two or three men, with battons of hard wood, into a pulp; which being put in water, ſeparates like grains of meal. Thus prepared, it is put into a narrow vat; an infuſion of Rice, and a mucous water of the infuſion of the root of Manihot being added to it. Theſe three are to be ſtirred with a clean ſlender reed, till reduced into a homogenous liquor, of a due conſiſtence. The prepared liquor is now put into a larger vat; from whence the ſheets are poured out one by one, and placed in heaps upon a table covered with a double mat; a ſmall thread of reed being placed between the ſheets at the edge, and projecting a little, ſo that they may be taken up ſingly when wanted; the heaps are covered with a plank of wood the ſize of the paper, upon which ſtones are put, at firſt of a light weight, but afterwards heavier, that all the wet may be preſſed out by degrees. The following day, the weights being removed, each ſheet is taken up by itſelf, and the operation is finiſhed[1].

The fineſt and whiteſt cloth, worn by the principal people at Otaheite and in the Sandwich iſlands is made of the bark of this tree: and this, when dyed red, takes a better colour. The Bread Fruit Tree makes a cloth inferior in whiteneſs and ſoftneſs, worn chiefly by the inferior people. Cloth is alſo made of a tree reſembling the wild Fig Tree of the Weſt Indies. It is coarſe and harſh, the colour of the darkeſt brown paper: but it is the moſt valuable becauſe it reſiſts water. This is perfumed and worn by the chiefs as a morning dreſs in Otaheite[2].

The juice of the Paper Mulberry is uſed in China as a glue in gilding either paper or leather, but not wood.

It was cultivated before 1759, by Hugh Duke of Northumberland[3], in whoſe gardens ſeveral of theſe trees were raiſed from ſeeds a few years paſt, and one of them was given to Mr. Miller.

4. The Virginian red or large-leaved Mulberry Tree with black ſhoots, [will grow to the height of thirty or forty feet, ſending forth many large branches. The leaves are not only larger but rougher than thoſe of the common Mulberry, though in other reſpects they ſomewhat reſemble them. It produces plenty of catkins, in ſhape like thoſe of the Birch, and it has a dark reddiſh fruit[4].] Mr. Miller remarks, that a large tree of this ſpecies which had been many years in the Biſhop of London's garden at Fulham, never produced any fruit, but had ſome years a great number of catkins, much like thoſe of the Hazel-nut, which occaſioned Mr. Ray to give it the name of Corylus: but it might be one of the male trees, which do not produce fruit, as ſometimes happens in the common ſort.

[According to Kalm, this tree is polygamous. The aments or catkins are the length of thoſe of the common or white Birch. The young leaves are very tomentoſe underneath; they are alſo frequently palmate, but generally three-lobed and ſubvilloſe[5].

Loureiro deſcribes it as a middle-ſized tree, with a ſmooth aſh-coloured bark, and long weak ſpreading branches. Leaves cordate, acute, ſerrate, large, pale, villoſe underneath, ſoft, petioled, alternate. Berry cylindric, an inch long, axillary, one or two together, pedunculed, red, eatable.

Parkinſon, ſo long ago as 1629, ſays that it grows quickly with us to a great tree, and that the fruit is longer and redder than the common ſort, and of a very pleaſant taſte. Though it bears the ſeverity of our climate very well, yet it is ſtill a ſcarce tree among us.

Native of Virginia and Carolina. According to Loureiro, it is alſo found wild to the weſt of Cochinchina, and is cultivated by the Cochinchineſe for feeding ſilkworms, but not ſo generally as the White Mulberry.]

5. This is a large tree, with a ſoft, thick, yelloviſh bark, and a milky juice like the Fig, which is aſtringent. The branches come out on every ſide. The leaves are on ſhort foot-ſtalks, rough, dark green above, pale underneath, alternate. Flowers in round heads, at the foot ſtalks of the leaves, on each ſide the branches, of an herbaceous white colour. Fruit roundiſh, firſt green, then white, and finally dark red. [It ſeems by Miller's deſcription to be a monoecous tree. Linnæus ſuſpects it to be dioecous. Loureiro deſcribes it as a ſhrub, ſix feet high, ſuberect and ſlender: the bark duſky and hempen; the branches few, long and weak. Leaves acute, commonly undivided, but ſome lobed, ſmooth, petioled, alternate. Berries roundiſh, duſky red, inſipid, ſmall, ſweet, axillary, ſolitary.

Native of the Eaſt Indies, Japan, and Cochinchina, where it is cultivated on a very extenſive ſcale, eſpecially on the banks of rivers, to feed ſilkworms.]

Mr. Miller received the ſeeds from Bombay, which ſucceeded in the Chelſea garden before the year 1759.

[6. This is a ſhrub irregularly branched, with a trunk ſeldom ſo big as the human arm: bark whitiſh gray: wood very hard, yellow, ſomewhat veined: branches ſlender, wand-like, round, ſmooth: branchlets leafy, bearing fruit at the baſe. Leaves of middling width, on very long petioles, commonly oval, rounded at the tip, very ſeldom acute, generally unequal at the baſe, entire and ſubcordate, very ſmooth, equally and ſtiffly ſerrate, moſtly entire; but ſometimes deeply five-lobed, ſinuate or three-lobed, or with only one ſinus, but diſtinguiſhable from the common Mulberry by the ſmoothneſs of the leaves. Berries ſmall, on long pedunculs, red or pale when ripe, inſipid; they are eaten freſh, in a conſerve or dried; a wine and a ſpirit are made from them in Siberia and Ruſſia, and the leaves are uſed for feeding ſilkworms[6].

Linnæus remarks, that it is very nearly allied to the preceding, but with longer pedunculs and petioles, the ſerratures of the leaves more diſtinct, and the fruit of Morus nigra.

7. This is a tall branching tree with a fine head, the whole abounding in a ſlightly glutinous milk of a ſulphureous colour. The timber is yellow and is uſed in dyeing. Spines awl-ſhaped, ſolitary, few; entire branches are frequently without any. Leaves acuminate, ſerrate, ſmooth on both ſides, veined, diſtich, on ſhort petioles, of various ſizes. Aments ſolitary, pendulous, axillary between the petiole and the ſpine, two or three inches in length, cylindric and very cloſe. Female flowers on a different tree, collected into a globe: their receptacles axillary, glaucous-green, ſolitary, with ſhort petioles. Among the female flowers are ſome chaffy bodies, which perhaps were flowers ſuffocated by their neighbours and dried up. Fruit yellowith green, ſweet, and eaten chiefly by birds[4].

Linnæus remarks, after Jacquin and Loefling, that this ſpecies is always dioecous; the leaves ſmooth, the ſtyle ſingle, and the calyx not berried.

Browne ſays it is a fine timber wood, and a principal ingredient in moſt of our yellow dies, for which it is chiefly imported into Europe, where it is well known under the name of Fuſtick-wood. The berries are ſweet and wholeſome, but not much eaten except by birds, who are the chief planters of it.

[1] Kæmpfer. [2] Cook's Voyage, 2. 210. [3] Hort. kew. [4] Hunter's Evelyn. [5] Linn. [6] Pallas.

Native of Brazil, New Spain about Carthagena, Jamaica and other iſlands in the Weſt Indies. Cultivated in 1739, by Mr. Miller [a].]

Mr. Miller makes two ſpecies of this—Morus tinctoria (n. 5.) the true Fuſtick-wood, which grows naturally in moſt of the iſlands in the Weſt Indies, but in much greater plenty at Campeachy. It is one of the commodities exported from Jamaica, where it grows in greater plenty than in any other of the Britiſh iſlands.—Morus Xanthoxylum (n. 8.), inferior in ſize, the branches more ſlender, the leaves narrower, rounded at the baſe, ſerrate, and ending in acute points. At the foot-ſtalk of each leaf come out two ſharp thorns, which in the older branches grow to the length of two inches. The fruit is ſmaller.

This alſo is a native of Jamaica, and of the Bahama iſlands. The wood of it is cut, and ſold for the ſame uſe with the other, from which it has not been well diſtinguiſhed by botaniſts, [who ſtill regard them as the ſame, or at leaſt not as ſpecifically different.]

PROPAGATION AND CULTURE.

1. The White Mulberry may be propagated either from ſeeds or layers, as will be directed preſently for the Black Mulberry, and is equally hardy: but the moſt expeditious method of raiſing this tree in quantity is from the ſeeds, which may be procured in plenty from the South of France or Italy. The beſt way to ſow them in England is [to prepare a fine warm border of rich mellow earth, or if that is not eaſily to be had] to make a moderate hot-bed, arch it over with hoops, and cover it with mats. Sow the ſeeds towards the end of march in drills, covering them with light earth a quarter of an inch deep: in very dry weather water the bed gently and frequently, in the heat of the day ſhade it with mats, and cover it when the nights are cold. In five or ſix weeks the plants will come up, and being tender when they firſt appear, muſt be guarded againſt froſty mornings, which often happen in may. During ſummer keep them clean from weeds, [cover them from the extreme heat of the ſun, and continue to water them in dry weather.] In autumn cover them again, when the firſt froſts come, and continue to protect them through the firſt winter. The following march tranſplant them into the nurſery, there to remain two or three years, and then to be removed where they are to continue. [Or if not very ſtrong, they had better remain in the ſeed-bed two years before they are planted out in the nurſery, in rows at two feet and a half diſtance, and one foot and a half aſunder in the rows, there to continue till they are ſufficiently ſtrong to be planted out finally [b].]

The trees which are deſigned to feed ſilk-worms, ſhould never be ſuffered to grow tall, but rather kept in a ſort of hedge: and inſtead of pulling off the leaves ſingly, they ſhould be ſheared off together with their young branches, which is much ſooner done, and is not ſo injurious to the tree.

[It is ſurpriſing that this precept of Mr. Miller's has not been attended to, not only in England, but in many of the ſouthern parts of Europe, where making ſilk is of ſome conſequence, ſince the practice is followed in the Eaſt, and is in itſelf perfectly rational. Father Loureiro informs us, that in Cochinchina they root up the plants every third year, and make freſh plantations of the cuttings, becauſe the young ſhoots afford a more delicate food for the worms, and produce a finer ſilk. Sir George Staunton relates that in a part of China through which the Embaſſy paſſed, Mulberries were cultivated and reared with the greateſt care; and planted in rows, ten or twelve feet aſunder, in beds of a moiſt, but not inundated loamy earth, thrown about a foot high above the ſurface. The trees are frequently pruned or dwarfed, in order to make them produce a conſtant ſucceſſion of young ſhoots, and tender leaves [c]. Our planters recommend a dry ſoil for the Mulberry; but it appears from the authors juſt quoted that in China and Cochinchina, it is cultivated in a very moiſt one, by the ſides of of rivers, or where rice is grown in trenches between the rows of trees.

If the Paper Mulberry ſhould be found too tender for our climate, might not this or our Common Mulberry, cultivated in this way, throw out ſhoots tender enough to be converted into Paper, by the proceſs uſed in Japan for that purpoſe?

2. The Common or Black Mulberry has generally male flowers or catkins on the ſame tree with the fruit; but it often happens, that ſome of the trees which are raiſed from ſeeds, have generally male flowers, and produce no fruit; ſo that thoſe who plant theſe trees for their fruit, ſhould never make choice of ſuch as have been propagated by ſeeds, unleſs they have ſeen them produce fruit in the nurſery. It is alſo the ſureſt way to mark ſuch trees as are fruitful in the nurſery, at the time when the fruit is upon them, becauſe thoſe trees which are propagated by layers, are ſometimes of the male ſort; for I have ſeveral times obſerved, that ſome of the large branches of theſe trees have produced only catkins, when the other parts of the trees have been very fruitful; ſo that unleſs care is taken in the choice of the branches for making the layers, there is the ſame hazard as in ſeedling trees: nor ſhould the ſhoots which come out near the roots of old trees be ever laid down, for theſe rarely produce fruit until they have been planted many years, although the trees from which theſe were produced might be very fruitful. I have obſerved ſome trees which produced only catkins for many years after they were planted, and afterwards have become fruitful; the ſame I have obſerved in Walnut-trees, and my honoured friend the Chevalier Rathgeb, has informed me, that he has obſerved the ſame in the Lentiſk and Turpentine-trees.

The old Mulberry-trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; ſo that where there are any of theſe old trees, it is the beſt way to propagate from them, and to make choice of thoſe branches which are moſt fruitful. The uſual method of propagating theſe trees, is by laying down their branches, which will take root in one year, and are then ſeparated from the old trees; but as the moſt fruitful branches are often ſo far from the ground as not to be layed, unleſs by raiſing boxes or baſkets of earth upon ſupports for this purpoſe, the better way is to propagate them by cuttings, which, if rightly choſen and ſkilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a diſtance, and from the moſt fruitful branches. Theſe cuttings ſhould be the ſhoots of the former year, with one joint of the two years wood to their bottom: the cuttings ſhould not be ſhortened, but planted their full length, leaving two or three buds above ground. The beſt ſeaſon for planting them is in march, after the danger of hard froſt is over; they ſhould be planted in light rich earth, preſſing the ground pretty cloſe about them; and if they are covered with glaſſes, it will forward their putting out roots: but where there is not ſuch conveniency, the ground about them ſhould be covered with moſs, to prevent its drying; and where this is carefully done, the cuttings will require but little water, and will ſucceed much better than with having much wet. If the cuttings ſucceed well and make good ſhoots, they may be tranſplanted the following ſpring into a nurſery, where they ſhould be regularly trained to ſtems, by tying down ſtakes by each, to which the principal ſhoots ſhould be faſtened; and moſt of the lateral branches ſhould be cloſely pruned off, leaving only two or three of the weakeſt to detain the ſap, for the augmentation of the ſtem; for when they are quite diveſted of their ſide ſhoots, the ſap is mounted to the top, ſo that the heads of the trees grow too faſt for the ſtems, and become too weighty for their ſupport. In about four years growth in the nurſery, they will be fit to tranſplant where they are to remain; for theſe trees are tranſplanted with greater ſafety while young, than when they are of a larger ſize.

[a] Hort. kew.

[b] Theſe additions are from Dr. Hunter's notes on Evelyn's Sylva.

[c] Vol. 1. p. 422.

If the cuttings are planted in a bed fully expoſed to the ſun, it will be proper to arch the bed over with hoops, that they may be ſhaded with mats in the heat of the day during the ſpring, till they have put out roots; after which, the more they are expoſed to the ſun, the better they will ſucceed, provided the ground is covered with moſs or mulch to prevent its drying, for the ſun will harden the ſhoots, and thereby they will be in leſs danger of ſuffering by the early froſts in autumn; for when theſe are in a ſhady ſituation, they are apt to grow vigorouſly in ſummer, ſo will be replete with moiſture, and the early froſts in October frequently kill their tops; and if the following winter proves ſevere, they are often killed to their roots, and ſometimes are entirely deſtroyed. I have two or three times made trial of planting the cuttings of Mulberries on a hot-bed, and have found them ſucceed extremely well. This I was led to by obſerving ſome ſticks of Mulberry-trees which were cut for forks, and thruſt into the hot-bed, to faſten down the vines of Cucumbers, which, although they had been cut from the tree a conſiderable time, yet many of them put out roots, and ſhot out branches; cuttings therefore planted on a moderate hot-bed will take root much ſooner than in the common ground.

This tree delights in rich light earth, and where there is a depth of ſoil, as in moſt of the old kitchen gardens about London; in ſome of which are trees of a very great age, which are healthy and fruitful, and their fruit is larger and better flavoured than thoſe of younger trees. In a very ſtiff ſoil, or on ſhallow ground whether of clay, chalk or gravel, the trunk and branches are commonly covered with moſs, and the little fruit produced is ſmall, ill-taſted, and ripens late.

If this tree be planted in a ſituation where it is defended from the ſtrong ſouth and north-weſt winds, it will preſerve the fruit from being blown off; but this ſhelter, whether it be trees or buildings, ſhould be at ſuch a diſtance as not to keep off the ſun; for where the fruit has not the benefit of his rays to diſſipate the morning dews early, it will turn mouldy and rot upon the trees. There is never any occaſion for pruning theſe trees, more than to cut off any of the branches which may go acroſs others, ſo as to rub and wound their bark, by their motion occaſioned by the wind; for their ſhoots ſhould never be ſhortened, becauſe the fruit is produced on the young wood.

[For propagating the Mulberry by layers, a number of trees muſt be planted for ſtools two yards aſunder. A few ſtools will ſoon produce many layers, for they throw out plenty of young branches, when the head is taken off. When the ſtools have ſhot forth young wood fit for laying, in the beginning of winter let the earth be excavated round each ſtool, and let the preceding ſummer ſhoots be ſlit at a joint and laid therein, fixing them down with a peg, filling the interſtices with fine mould, levelling the ground, and cutting the young twigs to one eye above the ſurface. In the autumn following the layers will all probably have taken good root, and have made a conſiderable ſhoot in the ſtem, ſo that they will be ready for the nurſery ground, in which they are to be managed in the ſame way as the ſeedlings. The ſecond year after, the ſtools will have a freſh crop of young wood for laying.

Cuttings may be planted not only in march, but alſo in October. Theſe ſhould be ſtrong ſhoots of the laſt year's wood, and if a tree does not make ſuch ſhoots, it muſt be headed the year before for this purpoſe. The ſhoots ſhould be a foot and half long, and muſt be planted a foot deep, in a ſhady well-ſheltered place, and in a moiſt ſoil, well worked and fine.

Theſe trees may likewiſe be increaſed by cuttings planted at the end of june, or the beginning of july, in pots plunged up to their rims in the ſtove, where if water and ſhade be conſtantly afforded them, they will ſtrike roots and become good plants*.

* Marſhall on Planting, vol. 2. edit. 2.

If an old Mulberry-tree becomes a bad bearer, or caſts the fruit before it is ripe; cut a trench, two feet deep, round the tree, and about four feet from the trunk; fill it with freſh mould, enriched with cow-dung; and as the large roots may be raiſed without inconvenience, let the compoſt be put under them, ſo as to make the bed, over which the tree ſtands, as rich as poſſible. At the ſame time, let the old wood be cut from the head of the tree, that the young wood may have ſpace to grow in. Theſe operations being judiciouſly conducted, you will, in a few years, have an old tree converted into a young one. Obſerve alſo, that if you expect plenty of fruit, the ground muſt not be cropped near the tree, for the feeding fibres of the roots will be cut off by the ſpade, when the fruit requires the greateſt nouriſhment*.

The Mulberry is remarkable for putting out its leaves late; ſo that when they appear, the gardener may take it for granted that all danger from froſt is over. This is a remark of Pliny's. *Cum germinare videris Morum, injuriam poſtea frigoris timere nolito.*

On the 22d of may, 1798, when I am writing this article, the ſeaſon being early and uncommonly genial, the Hawthorn having bloſſomed on the firſt of the month, the leaves of the common Mulberry are now expanding with great caution, a few only at the extremities of the branches being almoſt as big as a ſhilling. Some of the Aſh-trees are nearly in the ſame ſtate; which I mention becauſe it is ſaid that Aſh leaves are uſed in China as a ſuccedaneum for thoſe of the Mulberry in feeding ſilkworms.]

3. Paper Mulberry may be propagated by ſeeds, or by laying down the branches, or by cuttings, in the manner directed for the common ſort. In Japan it is cultivated for making paper of the bark much after the ſame manner as Oſiers are cultivated here, cutting down the young ſhoots at the end of the year, when the leaves are off.

4. This tree has not been propagated yet in this country, for though it has been budded and grafted upon the White and Black Mulberry, it has not ſucceeded. Being tall, it cannot well be laid down, which is the moſt likely method to propagate it. This is very hardy, and will endure the cold of our climate in the open air very well.

5. This is too tender to live out of the Bark-ſtove, where it muſt be treated as other tender plants, giving it but little water in winter. With this management it will retain its leaves all the year.

6. Culture and management the ſame as the firſt and ſecond ſorts.

7. This muſt be preſerved in the Bark-ſtove. The ſeeds come up freely in a hot bed: when the plants are fit to remove, plant each in a ſeparate ſmall pot filled with freſh light earth, and plunged into a hot-bed of tanner's-bark, ſhading them from the ſun till they have taken new root; and then treating them as other plants from hot countries. They retain their leaves great part of the year in the ſtove.

MOULD, or vegetable earth, the goodneſs of which may be known by the ſight, ſmell, and touch.

Firſt, by the ſight: thoſe Moulds that are of a bright cheſtnut, or hazelly colour, are counted the beſt; of this colour are the beſt loams, and alſo the beſt natural earth, and this will be better yet, if it cuts like butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall clods, is ſweet, will be tempered without cruſting or chapping, in dry weather, or turning to mortar in wet.

The next to that, the dark gray and ruſſet Moulds

* Hunter on Evelyn.

are accounted the beſt, the light and dark Aſh-colour are reckoned the worſt, ſuch as are uſually found on common, or heathy ground; the clear tawny is by no means to be approved, but that of a yellowiſh red colour is accounted the worſt of all: this is commonly found in wild and waſte parts of the country, and for the moſt part produces nothing but Furz and Fern, according as their bottoms are more or leſs of a light and ſandy, or of a ſpewy gravel, or clayey nature.

Secondly, by the ſmell: all lands that are good and wholeſome, will, after rain, or breaking up by the ſpade, emit a good ſmell.

Thirdly, by the touch: by this means we may diſcover whether it conſiſts of ſubſtances entirely arenaceous, or clammy; or, as it is expreſſed by Mr. Evelyn, whether it be tender, fatty, deterſive, or ſlippery, or more harſh, gritty, porous, or friable.

That being always the beſt that is between the two extremes, and does not contain the two different qualities of ſoft and hard mixed, of moiſt and dry, of churliſh and mild, that is neither too unctuous or too lean, but ſuch as will diſſolve, of a juſt conſiſtence, between ſand and clay, and ſuch as will not ſtick to the ſpade or fingers upon every flaſh of rain.

A loam, or brick Mould, is not to be diſapproved, as requiring little help or improvement but the ſpade, and is eſteemed both by the gardener and floriſt.

SEEDS ſolitary, compreſſed, kidney-form, ſmooth.

ESSENTIAL CHARACTER.

Pericarp elongated, fleſhy, necklace-form, with one-ſeeded globules.

SPECIES.

1. Mullera moniliformis.
Lin. ſyſt. 667. *ſuppl.* 329. *Mer. ſurin. t.* 35.

DESCRIPTION, *&c.*

This is a tree with ferruginous, ſomewhat warted branches. Leaves alternate, pinnate, having two pairs of leaflets with an odd one at the end. Leaflets equal, oppoſite, petioled, ovate-oblong, like thoſe of Privet, quite entire, acute, ſmooth above, ſilky underneath, flat, veined: petioles elongated, round, with a thickened joint at the baſe where they are inſerted. Stipules none. Racemes axillary and terminating, ſimple, the length of the petioles. Bractes none. Flowers ſcattered, nodding, the ſize of Laburnum flowers. The petals fall off, whilſt the calyx remains, and the germ ſwells: this however does not become a fruit, but it is lengthened out, and from it, as from a receptacle, come out ſeveral globules, flatted a little and in a chain, no veſtige of which is in the flower. At firſt they are the ſize of a Lentil ſeed, and when perfect they are as big as a large Plum: they are exactly ſpherical, very ſmooth, and ſeparated from the receptacle by a petiole: from the top of each globule iſſues a ſhort petiole uniting it to the next, and ſo on: no future is apparent in the globules, nor are they cloven as in the proper legume; but they are compoſed of a thick hard ſubſtance, in the middle of which is a cavity, as in oblong Plums, filled with one kidney-form ſeed, the ſize of a large Kidney Bean, with the hilum or umbilical ſcar at the angle, as in leguines.

This plant has a near affinity to Sophora, but it differs from it in having the ſtamens properly diadelphous, and the fruit not leguminous, or opening longitudinally by two valves.

Native of Surinam[b].

Lin. ſyſt. 697. *Reich.* 3. 586. *mant.* 243. *Murr. prodr. præf. cum ic. Munch. hauſo.* 5. 357. *t.* 356.

DESCRIPTION, *&c.*

This is a ſmall tree, with alternate, patulous, round, ſmooth branches. Leaves alternate, ovate or ovate-oblong, acuminate, quite entire, ſmooth, paler underneath; on very ſhort petioles. Stipules none. Racemes terminating, ſomewhat branched, erect, a foot long, ſtrict, round, ſmooth. Flowers alternate, on very ſhort peduncles, extremely handſome. Calyxes ſubtomentoſe, with ſix channelled ſwellings. Petals four times as large as the calyx. Stamens half the length of the petals. Style at firſt equal to the ſtamens, but afterwards longer[1].

Native of Java and China. Cultivated in the Upſal garden in 1748, and flowered there the year following[2].—See *Lagerſtroemia.*

[1] Murr. prodr. præf. a Linn. [2] Murr. prodr. præf.

DESCRIPTION, *&c.*

[This ſhrub or ſmall tree riſes from a fathom to ten or twelve feet, or according to Sloane thirty feet in height, ſending out many irregular, ſpreading, long, round, hairy branches, covered with a ſmooth dark purple bark, with diſtich ſlender branchlets or twigs ſet alternately. Leaves alternate, flat, ſpreading horizontally, oblique, ovate lanceolate, acuminate, unequally ſerrate, nerved, green and hirſute above, hoary-tomentoſe and viſcid underneath, three, four or five inches long and three quarters of an inch broad at the baſe; the upper ones more oblique, or ſtretching much farther back on one ſide of the petiole than they do on the other. Petioles ſhort, round, hirſute. Stipules ſolitary, the length of the petioles, filiform, hirſute in front at the baſe of the leaves. The hairs of the leaves are glandular. Peduncles two to four, between the petioles, and not axillary, cluſtered, longer than the petiole, ſhorter than the leaf, one-flowered, round, villoſe-viſcid. Jacquin remarks, that they ſucceſſively turn the flower when it is about to expand to the face of the leaf, which before was reflexed to the back of it. Flowers without ſcent but handſome, an inch in diameter, reſembling thoſe of the Bramble, according to Sloane. The calyx is aſh-coloured, and the petals are white. The former is five or ſix-parted; the parts the ſame length with the petals, hirſute, and viſcid: the latter five or ſix in number with a very ſhort claw, and plaited. Filaments twenty-five to thirty, ſhorter than the germ. Anthers twin. Germ ſmooth. Stigma five or ſix-cornered, five or ſix-rayed[1]. Berry ſpherical, crowned with the ſeſſile ſtigma, which has from four to ſix grooves, ſucculent, many-celled: partitions membranaceous, very thin, ſubdivided towards the periphery, when the cells are unequal and irregular. Seeds very ſmooth and ſhining, whitiſh or pale ſtraw-colour, neſtling in the pulp without any receptacle[m]. According to Jacquin, the berry is roſe-coloured with a tinge of yellow, and when cut tranſverſely ſeems to be one-celled, but if the pulp and ſeeds be gently preſſed out in water, it appears very clearly to be five-celled. Sloane ſays, the fruit is as big as a Cherry, and Miller] that it is as large as that of the Cockſpur Hawthorn; of a dark purple colour, when ripe.

Native of Jamaica, on the calcareous ſubalpine hills, flowering in the ſpring[n]: and of St. Domingo, in the wet parts of woods, flowering in auguſt and ſeptember[o].

This is not the Mullam Toddali of Rheede, hort. malab. as Linneus thought it was, for that is of a different genus, and has nothing in common with Muntingia Calabura, but a ſlight agreement in the leaves[p].]

The ſeeds of this plant were ſent by Mr. Robert Millar from Jamaica, which ſucceeded in ſome of the Engliſh gardens.

PROPAGATION AND CULTURE.

This plant is propagated by ſeeds, which ſhould be ſown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanner's bark, and in warm weather the glaſſes ſhould be raiſed to admit freſh air. Theſe ſeeds will often remain in the ground a whole year before the plants will appear; in which caſe the pots muſt be kept conſtantly clear from weeds, and ſhould remain in the hot-bed till after michaelmas, when they may be removed into the ſtove, and plunged into the bark-bed, between other pots of tall plants, where they may remain during the winter ſeaſon. Theſe pots ſhould be now and then watered, when the earth appears dry, and in the beginning of march the pots ſhould be removed out of the ſtove, and placed in a freſh bark-bed under frames, which will bring up the plants ſoon after.

When the plants are come up about two inches high, they ſhould be carefully taken out of the pots, and each planted into a ſeparate ſmall pot filled with light rich earth, and then plunged into the hot-bed again, obſerving to ſhade them from the ſun until they have taken new root, after which time they ſhould

[1] Swartz, Jacquin. [m] Gærtner. [n] Swartz. [o] Jacquin. [p] Gærtner.

be duly watered, and in warm weather they muſt have a large ſhare of freſh air. In this hot-bed the plants may remain until autumn, when the nights begin to be cold; at which time they ſhould be removed into the ſtove, and plunged into the bark-bed. During the winter ſeaſon theſe plants muſt be kept warm, eſpecially while they are young, and frequently refreſhed with water; but it muſt not be given to them in large quantities leſt it rot the tender fibres of their roots. It will be proper to continue theſe plants in the ſtove all the year, but in warm weather they ſhould have a large ſhare of freſh air; but as the plants grow in ſtrength, they will be more hardy, and may be expoſed in ſummer for two or three months, and in winter will live in a dry ſtove, if kept in a moderate degree of heat.

Marſana buxifolia. *Sonner. ind.* 2. 245. *t.* 139.

Chalcas japonenſis. *Leur. cochinch.* 271.

DESCRIPTION, *&c.*

This is a tree of the ſmalleſt ſize, with a whitiſh bark, and the appearance of Schinus. Leaves alternate, petioled, ſomewhat rigid, unequally pinnate. Leaflets ſeven, petioled, alternate, obovate, ſmooth, bluntiſh. It was thought to be a very different plant from Chalcas paniculata[a], but it proves to be the ſame ſpecies. Loureiro however has two. Berry juiceleſs, ſuperior, globular, terminated by a ſhort point, obſcurely ſhagreened by raiſed dots or miliary tubercles, leathery, thin, one-celled. Seed almoſt the ſize of the berry, ſubglobular, covered all over with very ſhort ſoft fibres, preſſed cloſe to it, whitiſh or pale ſtraw-colour, fixed to the bottom of the berry, and cohering to it all round by its cuticle[b].

Native of the Eaſt Indies. Introduced in 1771, by Benjamin Torin, Eſq. It flowers in auguſt and ſeptember[c].]

[a] Linn. mant. [b] Gærtner. [c] Hort. kew.

GENERIC CHARACTER.

* *Hermaphrodite* flowers more, towards the baſe of the ſimple Spadix, ſeparate in alternate ſpathes.

CAL. *Spathe* partial ovate-oblong, plano-concave, large, many-flowered.

COR. unequal, ringent: the petal conſtituting the upper lip, but the nectary the under lip. *Petal* erect, ligulate, truncate, five-toothed, converging in front at the baſe.

Nectary one-leafed, cordate, boat-ſhaped, compreſſed, acuminate, ſpreading outwards, ſhorter than the petal, inſerted within the ſinus of the petal.

STAM. *Filaments* ſix, awl-ſhaped, five of which within the petal are erect, the ſixth within the nectary is reclining. *Anthers* linear, from the middle to the top faſtened to the filament; but moſt frequently there is only one anther on the ſixth filament, and very ſmall ones or none on the reſt.

PIST. *Germ* very large, obtuſely three-ſided, very long, inferior. *Style* cylindric, erect, the length of the petal. *Stigma* headed, roundiſh, obſcurely ſix-cleft.

PER. *Berry* fleſhy, covered with an huſk, obſcurely three-ſided or ſix-ſided, gibbous on one ſide, one-celled, hollow in the middle.

SEEDS very many, neſtling, ſubglobular, wrinkled-tubercled, excavated at the baſe. *G.* or only rudiments.

* *Males* on the ſame Spadix, above the Hermaphrodite flowers, ſeparated by Spathes.

CAL. COR. and NECT. as in the Hermaphrodites.

STAM. *Filaments* as in the Hermaphrodites, equal, erect. *Anthers* as in the Hermaphrodites, on the filament placed within the nectary, moſt frequently very ſmall or none.

PIST. *Germ* as in the Hermaphrodites, but leſs. *Style* and *Stigma* as in them, but leſs and more obſcure.

PER. is abortive.

SEEDS

OBS. *The flowers, often monſtrous, vary much in the number of parts of the corolla, ſtamens and anthers both perfect and imperfect; they do not always therefore agree exactly with Linnæus's deſcription. Scopoli obſerved five ſtamens only. Berry of* M. Troglodytarum *three-celled.*

ESSENTIAL CHARACTER.

Cal. Spathe partial many-flowered. *Cor.* two-petalled; one petal erect five-toothed, the other nectariferous concave ſhorter. *Stam.* ſix. *Style* one. All the flowers *hermaphrodites*.

Male Herm. above; five filaments perfect. *Germ* inferior, abortive.

Fem. Herm. one filament only perfect. *Berry* oblong, three-ſided, inferior, many-ſeeded.

DESCRIPTIONS, *&c.*

Root a perennial roundifh folid watery bulb, dufky on the outfide, white within; with a few thick fibres. Stem biennial, fometimes longer lived, from five to twenty feet in height, upright, very ftraight, quite fimple, thick, round, fmooth, fungous, watery, lamellated: the lamellæ convoluted, each ending in long channelled embracing petioles, imbricate at the bafe. Leaves oblong, blunt, quite entire, from three to ten feet in length, and lefs than two feet in width, having many tranfverfe ftreaks or grooves, fmooth, bright green, readily divifible at the grooves. Flowers terminating, whitifh, in one very large raceme or bunch, moft commonly reflex, thick, round, compound: racemelets alternate, feffile, with the flowers extended in breadth in a double row. General calyx none: partial of each racemelet a fpathe, which is fubacute, concave, grooved, purplifh, opening fucceffively, deciduous. Proper perianth none. Petals two: outer erect, blunt, five-toothed and reflex at the end; inner boat-fhaped, quite entire, fhorter, reflex at the bafe. In the fertile flower five filaments, which are awl-fhaped, fhorter than the erect petal, fitting on the receptacle: of thefe one or two, fometimes all, are antheriferous: anthers linear, lateral. Germ oblong, inferior, bluntly three-cornered. Style linear, thick, longer than the ftamens. Stigma headed, grooved at the top. Berry oblong, fomewhat angular, fleffhy, fweet, eatable, three-celled; containing many roundifh black neftling feeds. The barren flower has alfo five filaments, of which frequently all, often fome only, fometimes none are antheriferous; the corolla is like that of the fertile flower: ftyle, ftigma, and germ fmall and abortive. The fertile flowers always occupy the lower, and the barren ones the upper part of the raceme: both are always deciduous, as are alfo the fpathes, except the uppermoft and outmoft, which rot within the fpathes [a].

They are natives of hot climates only, and are generally cultivated within the tropics. They do not however feem to have been indigenous of America.]

1. This plant rifes with a foft herbaceous ftalk fifteen or twenty feet high, and upward; the lower part of the ftalk is often as large as a man's thigh, diminifhing gradually to the top, where the leaves come out on every fide, which are often more than fix feet long, and near two feet broad, with a ftrong fleffhy midrib, and a great number of tranfverfe veins running from the midrib to the borders. The leaves are thin and tender, fo that where they are expofed to the open air, they are generally torn by the wind; for as they are large, the wind has great power over them: thefe leaves come out from the fide of the principal ftalk, inclofing it with their bafe; they are rolled up at their firft appearance, but when they are advanced above the ftalk they expand quite flat, and turn backward; as thefe leaves come up rolled in the manner before mentioned, their advance upward is fo quick, that their growth may be almoft difcerned by the naked eye; and if a line is drawn acrofs, level with the top of the leaf, in an hour's time the leaf will be near an inch above it. When the plant is grown to its full height, the fpike of flowers will appear from the centre of the leaves, which is often near four feet in length, and nods on one fide. The flowers come out in bunches, thofe on the lower part of the fpike being the largeft; the others diminifh in their fize upward; each of thefe bunches is covered with a fpatha or fheath, of a fine purple colour within, which drops off when the flowers open. The upper part of the fpike is made up of male or barren flowers, which are not fucceeded by fruit. The fruit is eight or nine inches long, and above an inch diameter, a little incurved, and has three angles; it is at firft green, but, when ripe, of a pale yellow colour. The fkin is tough, and within is a foft pulp of a lufcious fweet flavour. The fpikes of fruit are often fo large as to weigh upwards of forty pounds.

[Native of the Eaft Indies, and other parts of the Afiatic continent, probably alfo of Africa. Cultivated generally between the tropics.] Said to be tranfported to the Weft Indies from the Canary iflands, to which it is believed that it was carried originally from Guinea. [It feems to have migrated with mankind from Afia into the numerous iflands of the fouthern Pacific Ocean, where it is univerfal in all the iflands that are inhabited, and has degenerated into numerous varieties. It was not known in America before the arrival of the Spaniards [b].

It was cultivated here in 1690, in the royal garden at Hampton-court, and commonly flowers with us from october to december [c]. Johnfon the editor of Gerarde's herball, fays that april 10, 1633, his much honoured friend Dr. Argent, then prefident of the College of Phyficians in London, gave him a plant of the Mufa, which he received from the Bermudas. The fruit on it was unripe, but he hung up the ftalk with the fruit thereon in his fhop, where it became ripe about the beginning of may, and lafted until june; the pulp was very foft and tender, and it did eat fomewhat like a Mufk Melon. Gerarde and other old authors name it *Adam's Apple-tree*, from a notion that it was the forbidden fruit of Eden; whilft others fuppofed this fruit to have been the Grapes brought out of the promifed land to Mofes.

Dampier thus fpeaks of it.—The Plantain is the king of all fruit, not excepting the Coco itfelf. The tree is three feet, or three feet and a half round, and ten or twelve high. It is not raifed from feed, but from the roots of other old trees. If thefe young fuckers are taken out of the ground, and planted in another place, it will be fifteen months before they bear, but if let ftand in their own native foil they will bear in twelve months. As foon as the fruit is ripe the tree decays, and many young ones grow up to fupply its place. The fruit of it is fo excellent, that the Spaniards give it the preference to all others, as moft conducing to life. It grows in a cod fix or feven inches long, and as big as a man's arm; the rind is foft, and yellow when ripe. It refembles in fhape a hog's pudding. The inclofed fruit is no harder than butter is in winter, and much of the colour. It is of a delicate tafte, and melts in one's mouth like marmalet. It is all pure pulp, without any feed, kernel or ftone. The fruit is fo much efteemed by all Europeans that fettle in America, that when they make a new plantation, they commonly begin with a good Plantain-walk; enlarging it as their family increafes. Some or other of the trees are bearing moft part of the year; and this is many times the whole food on which a family fubfifts. They thrive only in rich flat ground; poor fandy foil will not bear them. When this fruit is ufed only for bread, it is roafted or boiled when it is juft full grown, but not yet ripe, or turned yellow. The Indians and Negroes eat them in a variety of ways, both raw and dreffed, freth and preferved: they alfo make a fermented liquor with them, which they drink always new. The ordinary people of Mindanao wear no other cloth, but what is made from the fibres of the trunk.

There is another fort in Mindanao, fhorter and leff than the other. Thefe are full of black feeds mixt quite through the fruit. They are binding, and much eaten by thofe that have fluxes.

In the Weft Indies the fruit is generally ufed when full grown, but before it ripens: it is commonly peeled and roafted, and is thus diftributed among the negroes, by whom it is mottly ufed; though many of the whites prefer it to any of the bread kind, efpecially whilft young and tender. The negroes generally boil it with other meffes, as falt-fifh, beef, pork, pickle or crabs, and find it a hearty wholefome food. As the fruit

[a] Loureiro.

[b] Forfter elcul.

[c] Hort. kew.

ripens, it becomes ſoft and ſweetiſh, and is then generally made into tarts, or ſliced and fried with butter. The juice of the tree is a very rough aſtringent. The leaves are generally uſed to dreſs bliſters; and when dried are made into mats, or employed to ſtuff matraſſes [a].

The Spaniards dry and preſerve the fruit as a ſweetmeat. The ripe fruit and maize together are the beſt food for hogs put up to fat, and give them a moſt exquiſite flavour and firmneſs. On thruſting a knife into the body of the plant, the aſtringent limpid water that iſſues out is given with great ſucceſs to perſons ſubject to a ſpitting of blood, and in fluxes [b].

The fruit of ſome out of the many varieties is eaten in the iſlands of the South Seas raw, of others roaſted or baked, according to their different qualities. The trees which bear the former are the chief ornaments of the gardens in Otaheite; the latter are in the mountainous tracts of the iſlands, that are covered with woods. This fruit is eaſy of digeſtion, very wholeſome and agreeable to ſeamen after a long voyage: to many however its clammy ſweetneſs is unpleaſant; and it is reputed to diſagree with weak ſtomachs, to bring on a conſtipation and flatulency in the bowels. Rumphius is of opinion, that whether crude or mature, this fruit, running readily into putreſcence, increaſes the malignity of the humours in the epidemic dyſentery [c].

2. The Banana or Bonana tree, as it is ſometimes written, differs from the preceding in having its ſtalks marked with dark purple ſtripes and ſpots. The fruit is ſhorter and rounder, with a ſofter pulp of a more luſcious taſte. [Dampier ſays the Banana is leſs luſcious than the Plantain, yet of a more delicate taſte. According to Long, it has a ſofter, mellower taſte, and is more proper for fritters than the Plantain. A very excellent drink is made from the juice of the ripe fruit fermented, moſt reſembling the beſt Southam cyder. A marmalade is likewiſe made of it, eſteemed an excellent pectoral, cooling and refreſhing.

The Banana fruit ripe, has been noted for its efficacy in correcting thoſe ſharp humours, which generate, or accompany the fluxes, to which Europeans are often ſubject on their firſt coming into the Weſt Indies. The roaſted fruit would be an uſeful ſea ſtore, would keep a long time, packed in dry leaves, and ſtowed in tight caſks; and would require only a freſh roaſting or heating, when wanted for uſe.—It was cultivated in 1731, by Mr. Miller.

Theſe two fruits are among the greateſt bleſſings beſtowed by Providence upon the inhabitants of hot climates. Three dozen Plantains are ſufficient to ſerve one man for a week inſtead of bread, and will ſupport him much better [d].

Though the Plantain and Banana are generally conſidered as different, yet Loureiro, Forſter and Gærtner cannot find any certain ſpecific diſtinction, and agree that Linnæus's is inſufficient. Gærtner unites them under the character of a one-celled berried fruit, which ſeparates them from Muſa Troglodytarum, that having a three-celled berried fruit.

There are many varieties of Plantain and Banana, as might be expected in plants ſo extenſively cultivated. Rumphius has ſet down ſixteen, which he obſerved in the Molucca iſlands. Forſter has enumerated theſe: and Loureiro has four ſpecies with ſeveral varieties, beſides Muſa Troglodytarum.

3. Stem four feet high, an inch in thickneſs. Leaves linear, three feet long, and five inches wide. Spathes linear, alternate, ſcarlet, many. Berry ſcarlet, ovate, compreſſed, two inches long, not eatable [e]. Gærtner deſcribes it as columnar, drawn to a point at both ends, curved, hexangular, leathery-fleſhy, very ſmooth, yellowiſh-green, three-celled: partitions membranaceous, thickiſh, meeting and connected near the axis. Seeds numerous, in a double row in each cell, fixed to the axis of the fruit, variouſly angular, jointed into one another as it were like the ſtones of a pavement, without any pulp between them, acuminate towards the umbilicus, very ſmooth, ferruginous or blackiſh.

Thunberg ſays that they are almoſt as large as Linſeed or the ſeed of Flax. Gærtner aſſerts, that this is a genuine ſpecies of Heliconia.

Native of the Molucca iſlands.]

PROPAGATION AND CULTURE.

In Europe there are ſome of theſe plants preſerved in the gardens of curious perſons, who have hot-houſes capacious enough for their reception, in many of which they have ripened their fruit very well; but as they grow very tall and their leaves are large, they require more room in the ſtove than moſt people care to allow them: they are propagated by ſuckers, which come from the roots of thoſe plants which have ſhifted; and many times the younger plants, when they are ſtinted in growth, will put out ſuckers; theſe ſhould be carefully taken off, preſerving ſome fibres to their roots, and planted in pots filled with light rich earth, and plunged into the tan-bed in the ſtove: theſe may be taken off any time in ſummer, and it is beſt to take them off when young, becauſe if their roots are grown large, they do not put out new fibres ſo ſoon, and when the thick part of the root is cut in taking off, the plants often rot.

During the ſummer ſeaſon theſe plants muſt be plentifully watered, for the ſurface of their leaves being large, there is a great conſumption of moiſture, by perſpiration in hot weather, but in the winter they muſt be watered more ſparingly, though at that ſeaſon they muſt be often refreſhed, but it muſt not be given them in ſuch quantities.

The pots in which theſe plants are placed, ſhould be large in proportion to the ſize of the plant, for their roots generally extend pretty far, and the earth ſhould be rich and light. The degree of heat with which theſe plants thrive beſt, is much the ſame with the Anana, or Pine Apple, in which I have had many of theſe plants produce their fruit in perfection, and they were near twenty feet high.

The moſt ſure method to have theſe plants fruit in England is, after they have grown for ſome time in pots, ſo as to have made good roots, to ſhake them out of the pots with the ball of earth to their roots, and plant them into the tan-bed in the ſtove, obſerving to lay a little old tan near their roots for their fibres to ſtrike into, and in a few months the roots of theſe plants will extend themſelves many feet each way in the bark; and theſe plants will thrive a great deal faſter than thoſe which are confined in pots or tubs. When the bark-bed wants to be renewed with freſh tan, there ſhould be great care taken of the roots of theſe plants, not to cut or break them, as alſo to leave a large quantity of the old tan about them, becauſe if the new tan is laid too near them, it will ſcorch their roots, and injure them: theſe plants muſt be plentifully ſupplied with water, otherwiſe they will not thrive; in winter they ſhould be watered twice a week, giving at leaſt two quarts to each plant, but in ſummer they muſt be watered every other day, and double the quantity given to them each time. If the plants puſh out their flower-ſtems in the ſpring, there will be hopes of their perfecting their fruit; but when they come out late in the year, the plants will ſometimes decay before the fruit is ripe. The ſtoves in which theſe plants are placed ſhould be at leaſt twenty feet in height, otherwiſe there will not be room for their leaves to expand; for when the plants are in vigour, the leaves are often eight feet in length, and two feet broad: ſo that if the ſtems grow to be fourteen feet to the diviſion of the leaves, and the houſe is not twenty feet high, the leaves will be cramped, which will retard the growth of the plants; beſides, when the leaves are bent againſt the glaſs, there will be danger of their breaking them, when they are growing vigorouſly; for I have had in one night the ſtems of ſuch bent leaves force through the glaſs, and by the next morning advanced two or three inches above the glaſs.

I have ſeen ſome bunches of fruit of the firſt ſort, which were upwards of forty pounds weight, and perfectly ripe in England; but this is not ſo good a fruit, as to tempt any perſon to be at the expence of raiſing them in England. The ſecond ſort is preferred to the firſt,

[a] Browne. [b] Long, jam. 782. [c] Forſter. [d] Long, jam. 783. [e] Loureiro.

first, for the flavour of its fruit, in all thoſe hot countries where theſe plants abound: the bunches of theſe are not near ſo large as thoſe of the firſt ſort, nor are the ſingle fruit near ſo long; theſe change to a deeper yellow colour as they ripen, but their taſte is ſomewhat like that of meally figs. Some perſons who have reſided in the Weſt-Indies, having eaten ſome of theſe fruit which were produced in England, thought them little inferior to thoſe which grew in America; and I imagine, that the inhabitants of thoſe countries would not eſteem theſe fruits ſo much, had they variety of other ſorts; but, for want of better, they eat many kinds of fruit, which would not be valued in Europe, could they be obtained in perfection.

[The Plantain Tree is cultivated with great care in all our ſugar-colonies. It thrives beſt in a cool, rich, moiſt ſoil, and is commonly planted in regular walks or fields: it is propagated by the ſhoots, and planted at convenient diſtances; but as the root throws up a number of young ſhoots every year, the ſpaces between the firſt plants are left pretty conſiderable. When the fruit is ripe, the ſtem decays gradually, and the root begins to throw up young ſhoots. The ſtem is then uſually cut down near the root, to give a ſtronger and quicker growth to the new plants[1].

In the South Sea iſlands, they put ſome wood aſhes and burnt plants with a little ſhell lime into the hole, when they plant the Muſa, by which they ſo accelerate the growth, as to have fruit in ſix and even four months; whereas in the common courſe it is eighteen months before fruit is expected[2].

MUSCORNIS. See *Muium* and *Jungermannia*.]

MUSCUS, Moſs. *Muſci*, Moſſes.

Formerly ſuppoſed to be only exreſcencies produced from the earth, trees, &c. but now known to be plants no leſs perfect than thoſe of greater magnitude. [They are ranged by Linneus in the ſecond Order of his twenty fourth Claſs, entitled *Cryptogamia Muſci*: but ſo much having been done to his hands on the ſubject of this Order by Dillenius, he did little more than arrange the ſpecies, and give them ſpecific characters.

Linneus has three diviſions of the Moſſes.—1. Without any Calyptre or Veil: containing the following genera—*Lycopodium*, *Porella*, *Sphagnum*. 2. Calyptred, diclinous, or having the males and females ſeparate—*Splachnum*, *Polytrichum*, *Mnium*. 3. Calyptred, monoclinous, or having the males and females on the ſame plant—*Phaſcum*, *Bryum*, *Hypnum*, *Fontinalis*, *Buxbaumia*.

Since the time of Dillenius and Linneus, great light has been thrown upon this obſcure order by Jacquin, Hoffman, Wiegel, Batſch, Pollich, Weis, Ehrhart, Schmidel, Schreber, Dickſon, Withering, Stackhouſe, &c. but eſpecially by Hedwig, who firſt communicated the reſult of his obſervations to the Academy of Sciences at Peterſburgh in the year 1783.

According to this laſt author, Moſſes are vegetables, in which the female parts of fructification are furniſhed with a veil-like petal, bearing a ſtyle. He divides them into two Orders:

1. *Capſule* entire, lidded, and opening tranſverſely: *Frondoſi*.

2. *Capſule* with four valves, opening lengthways: *Herbatici*.

The latter are not ranged with the *Muſci*, but with the *Algæ* by Linneus.

Theſe definitions of Hedwig exclude the *Lycopodium* from the Moſſes.

General Character of Muscı or Mosses.

* *Male* Flowers.

CAL. common, of many leaves: *leaflets* in ſtructure reſembling thoſe of the plant, but generally broader, ſometimes coloured, open and expanding like the rays of a ſtar, or the petals of a full-blown roſe, or elſe cloſing and approaching like a bud.—A few have no appearance of a calyx.

COR. none.

STAM. numerous, within the common calyx, moſtly ſeparated by ſucculent threads or chaff-like ſubſtances: ſometimes uniting ſo as to form a little knob, or placed in the axils of the upper branches. *Filament* ſhort, filiform. *Anthers* ſometimes cordate or ovate, but moſtly cylindrical, one-celled, opening at the top and diſcharging granulated pollen.

* *Female* Flowers, on the ſame or a different plant, ſometimes intermixed with the males.

CAL. *Perichætium* many leaved; *leaflets* various, generally incloſing ſeveral piſtils intermixed with ſucculent threads.

COR. *Veil* cylindrical or conical, inveſting the germ and fixed to its top, united at the baſe to the ſheath of the peduncle, but not elſewhere attached.

PIST. *Germ* cylindrical or conical. *Style* ſlender, ſtanding on the veil. *Stigma* truncate.

PER. *Capſule* on a peduncle ſheathed at the baſe, when unripe crowned by the veil which ſeparates at its baſe, adhering to the point of the capſule; but falling off when that becomes ripe. The capſule then opens horizontally, the lid ſeparating.

Lid with or without a ring, ſingle? or double; *outer* cartilaginous, ſometimes ſwollen, or elſe contracted at the baſe, forming a kind of excreſcence called *Apophyſis*.

Mouth of the capſule either naked, or cloſed with an outer fringe.

Outer fringe with from four to thirty-two teeth, which are upright or reflected, ſtraight or twiſted, triangular, ſpear-ſhaped or briſtle-ſhaped, ſharp or blunt.

Inner fringe finer, either cloſely adhering to the outer, or joined to it by threads from its inner ſide, or looſe and unconnected, or fixed to the pedicle on its little bulb. *Mouth* naked, or covered with a membrane or network of the inner fringe, or variouſly jagged, or cloſed by diſtinct and regular teeth. *Column* extending from the baſe to the point of the capſule, filiform, ſtraight, paſſing through the lid into the ſtyle, and often giving the lid a pointed appearance.

SEEDS numerous, minute, ſpherical, ſmooth or rough.

HABIT. *Stems* leafy. *Leaves* membranaceous, reticulated, after being dried reviving when ſoaked in water.

Obſervations.

If *Bryum pomiforme*, *ſubulatum* of Haller, *trichodes*, and a few others be excepted, Moſſes bear the ſtamens and piſtils in ſeparate flowers, either on the ſame, or on diſtinct plants.

The time of flowering generally coincides with that of the fruit attaining maturity, as happens in other evergreen perennials. Thus in *Polytrichum urnigerum*; *Mnium fontanum*, *bornum*, *punctatum*, *undulatum*; *Bryum trichodes*, *cæſpitilium*, &c. the veils fall off early in the ſpring, and the ſeed is ſcattered abroad; whilſt at the ſame time the leſs obvious unimpregnated germs, and the male or ſtameniferous flowers are performing their reſpective functions. This circumſtance cauſed theſe ripe capſules to be miſtaken for anthers, and the ſeeds for pollen.

Both male and female flowers are furniſhed with an involucre, which gives the outward figure to the flower, and is called the *Perichætium*. It varies more, and is more to be attended to in the male than in the female flowers. The radiated diſks of the Polytrichums and Mniums are very remarkable, and the ſcales compoſing them differ in many reſpects from the other leaves. The heads which put forth at the extremities of the Bryums have been hitherto unnoticed, though they contain the parts of fructification, and are compoſed of leaflets or ſcales different both in ſhape and ſize from the ſtem-leaves. Thus in *Bryum rurale* they are not terminated by hairs, and are ſhorter than the ſtem-leaves. In *Bryum pellucens*, *ſcoparium*, *heteromallum*, *aſiculare*, &c. they are broader than the other leaves, and more hollow at the baſe. Where the diſk-like ſubſtances form a kind of bud, as in almoſt all the *Hypnums*, *Bryum extinctorium*, *ſubulatum*, *pulvinatum*, *hypnoideum*, &c. they are much ſmaller than the leaves; they are alſo concave, ovate or ſpoon-ſhaped,

[1] Browne. [2] Forſter.

ſhaped, and deſtitute of the hairs which are on the real leaves[1]. Theſe therefore are truly the calyx, and as they include the florets with ſtamens only, they may be called the Perichætiums of the male florets.

On thoſe Moſſes which bear female flowers or capſules, the leaves adjoining to the peduncle are much more beautiful than thoſe on the ſtems: but ſometimes the inner leaves become gradually ſmaller, and thoſe neareſt to the flowers ſo very minute, that without a microſcope it is not poſſible to diſſect them away ſo as to expoſe the flower. Theſe therefore are to be conſidered as the involucres of the female flowers, ſurrounding and embracing the germ.

Male or ſtameniferous flowers.

The *Anthers* are almoſt univerſally cylindrical, either ſtraight or crooked; but in *Sphagnum paluſtre* and *Mnium androgynum*, they are ovate and more or leſs tapering to a point. Their colour is a very dilute green, almoſt white. When viewed under the higheſt magnifiers, and ſtrongly illuminated by reflected light, they are found to contain a granulated ſubſtance; but their tops are very pellucid, and this pellucid part expands into a riſing veſicle at the time the pollen is about to be diſcharged. The top then opens and the pollen is ejected, the ſpace from which it iſſues becoming more tranſparent. This pollen, when evacuated, ſeems to explode in the drop of water, in which theſe obſervations are to be made.

Beſides the anthers, included within the ſame involucre are ſome very delicate ſucculent bodies, of various ſhapes.

In *Polytrichum* and *Mnium* ſome of the barren florets are like diſks, others like roſes; and ſome like ſtars, when in a fully expanded ſtate. In the ſtellated Polytrichums the ſcales are placed in concentric circles. In *Mnium hornum, paluſtre, fontanum*, &c. they are more like a roſe or a diſk. After the pollen is diſperſed, theſe roſes or ſtars become more expanded; but previous thereto they are generally ſo open as to admit a view of the parts they contain. In ſome Moſſes the flowers terminate the branches, as in *Mnium pyriforme* and *purpureum*; *Bryum pellucidum, aciculare, ſcoparium, heteromallum, viridulum, ſimplex*, &c. in ſuch, though a little open, they are not enough ſo to allow a ſight of the anthers, until the flowering be paſt. Some florets are like buds, and ſit in the boſom of the leaves; others in the imbricated thickened termination of the branches, as in *Sphagnum*.

Female flowers.

Theſe are furniſhed with a germ, ſtyle and ſtigma; but being accompanied by other ſubſtances much reſembling them, they are difficult to be diſtinguiſhed until the germ begins to ſwell, in conſequence of its impregnation.

The piſtils, after impregnation, daily growing larger, and riſing upwards, ſhow the calyptra or veil, which may be conſidered as a kind of petal, and is perforated at the top by the ſtyle. This ſtyle is ſometimes permanent, falling off only with the veil itſelf; but where it is not ſo, the remains of it are always to be found.

It is evident, from what has been ſaid, that what Linnæus called the anthers, are really the ſeed veſſels: but by ſowing the ſeeds which they contain, a crop of young plants has been repeatedly procured, in all reſpects ſimilar to their parents[1].

Mr. John Lindſay, ſurgeon in Jamaica, ſowed the fine duſt from the fructification of *Lycopodium cernuum* and *Bryum cæſpitium* repeatedly, and in a proper ſituation found them to grow very readily. He alſo raiſed plants from the fine elaſtic filaments and ſmall globules, commonly conſidered as the male parts, of *Marchantia polymorpha*. This however is not now conſidered as a Moſs properly ſo called, but one of the *Hepaticæ*. Joſeph Fox alſo raiſed plants of *Lycopodium Selago* from ſeed. It is ſingular that Mr. Miller ſhould poſitively aſſert in the year 1768, that Moſſes cannot be propagated from ſeed by any art; and that a journeyman weaver of Norwich ſhould accompliſh it in the year 1779[2].

[1] Withering edit 3. 1. 356.
[2] Smith in Linn. tranſ. 2. 314.

The Capſules of Moſſes are always ſupported upon a peduncle, though ſometimes it is very ſhort, and excepting only in *Sphagnum paluſtre*, it is ſheathed and conical at its baſe. The capſules vary in ſhape, ſize and conſiſtence. In ſome ſpecies there is an elaſtic ring between the capſule and the veil, which when the ſeed is ripe, throws off the veil with more or leſs force. The veil being thrown off certain fringe-like proceſſes or projections appear, varying greatly in ſize, ſhape, ſtructure, number and diſpoſition: they ſurround the opening of the capſule in a ſingle or double, rarely in a triple ſeries. Theſe ſubſtances conſtitute the *Periſtoma*. The uſe of this Periſtoma or Fringe ſeems to be, to defend the ſeeds in wet weather. In dry weather it expands and leaves the mouth of the capſule open, but upon the leaſt moiſture, even that of the breath, it cloſes again.

The Seeds of Moſſes are ſpherical, generally ſmooth, ſometimes dotted, as in *Bryum extinctorium*, ſometimes prickly, as in *Bryum pyriforme* and *heteromallum*. They are brown, yelloviſh or greeniſh[1].

Some of the above obſervations being made with very high magnifiers are to be received with ſome degree of caution.

Uſes.

Moſſes thrive beſt in barren places. Moſt of them love cold and moiſture. Trifling and inſignificant as they are generally ſuppoſed to be, their uſes are by no means inconſiderable. They protect the more tender plants when they firſt begin to expand in the ſpring, as the experience of the gardener can teſtify, which teaches him to cover with moſs the ſoil and pots which contain his tendereſt plants; for it equally defends the roots againſt the ſcorching ſun beams and the ſeverity of the froſt. In the ſpring particularly the roots of young trees and ſhrubs are liable to be thrown out of the ground, eſpecially in light ſpongy ſoils: but if they are covered with moſs, this accident never can happen. They who raiſe trees from ſeed, will find an intereſt in attending to this remark.

Moſſes retain moiſture a long time without being diſpoſed to putrefy. The angler takes advantage of this circumſtance to preſerve his worms, and the gardener to keep moiſt the roots of ſuch plants as are to be tranſported to any conſiderable diſtance.

It is a vulgar error to ſuppoſe that Moſſes impoveriſh land. It is true they grow upon poor land which can ſupport nothing elſe; but their roots penetrate very little, in general hardly a quarter of an inch into the earth. Take away the moſs, and inſtead of more graſs there will be leſs: but if the land be drained and manured, the graſs will increaſe, and the moſs will diſappear.

Sphagnum paluſtre, Mnium triquetrum, Bryum paludoſum and *æſtivum, Hypnum adnexum, ſcorpioides, riparium* and *cuſpidatum* grow upon the ſides and ſhallower parts of pools and marſhes: in proceſs of time, occupying the ſpace heretofore filled with water, they are in their half-decayed ſtate, dug up and uſed as fuel, under the name of Peat. Theſe marſhes, drained partly by human induſtry, and partly by the long continued operations of vegetables, are at length converted into fertile meadows. Very few Moſſes are eaten by cattle. A few Moths feed upon ſome of them. Their medicinal virtues are but little known, and leſs attended to. It is probable, on account of their aſtringent properties, that ſome of them might be worth trying as a ſubſtitute for oak bark in tanning leather[2].

Moſſes are frequently very injurious to trees, particularly Fruit trees, which grow upon cold barren ſoils, or where they are ſo cloſe planted as to exclude the free acceſs of air. The only remedy in ſuch a caſe is to cut down part of the trees, and to plough up the ground between thoſe left remaining: and in the ſpring of the year, in moiſt weather, to ſcrape off the moſs, with an iron inſtrument made a little hollow, the better to ſurround the branches; and to carry it off the place: by cleanſing the trees thus two or three times,

[1] Withering, 1. 361. and Hedwig.
[2] Withering, 1. 362.

together with carefully ſtirring the ground, the moſs may be entirely deſtroyed: but if part of the trees be not cut down, and the ground well ſtirred, rubbing off the moſs will ſignify little; for the cauſe not being removed, the effect will not ceaſe, but the moſs will in a ſhort time be as troubleſome as ever.

Linnæus's genera have been ſplit into ſeveral others by Hedwig and the other reformers. Hypnum and Bryum were indeed ſo unwieldy that it was very deſirable they ſhould be divided. The genera of Moſſes as they ſtand in Schreber are *Phaſcum*, *Sphagnum*, *Gymnoſtomum*, *Tetraphis*, *Octoblepharis*, *Splachnum*, *Grimmia*, *Encalypta*, *Dicranum*, *Trichoſtomum*, *Didymodon*, *Tortula*, *Weiſſia*, *Poblia*, *Funaria*, *Bryum*, *Timmia*, *Meeſia*, *Bartramia*, *Fontinalis*, *Hypnum*, *Leſkia*, *Neckera*, *Buxbaumia*, *Polytrichum*. See their characters under theſe reſpective genera.

Other Moſſes were placed by Linnæus in his Order of *Algæ*; they are now ſeparated from that, and form a diſtinct Order, under the name of *Hepaticæ*.

In theſe, the *Female* fructifications are incloſed in a veil, which ſplits open at the top, and diſcharges the capſule. The *Capſule* opens lengthwiſe, and is filled with numerous *Seeds*, fixed to an elaſtic cord, formed of one or two ſpiral threads.

Some plants are referred to this ſubdiviſion on account of their agreement in general habit, though the female fructification has no veil, but is placed upon, or immerſed in the ſubſtance of the leaf.

The leaves are moſtly lobed, exhibiting a net-work of veſicles, and though dried, reviving again when moiſtened with water.

Hedwig obſerves that all the female florets have a double calyx, or a calyx and corolla. In ſhape and ſtructure he ſays they greatly reſemble the proper moſſes, but that he never found the ſucculent threads: the piſtil-like ſubſtances are however found, accompanying both the germ and ripened capſule; but not in all the ſpecies.

The Capſule, like thoſe of the true Moſſes, is incloſed in a veil, to which the ſtyle adheres; but this veil is not, as in them, looſened at its attachment and raiſed along with the growing capſule; it tears open in two, three or four places, and has therefore been ſometimes conſidered as a petal.

All theſe Moſſes agree in ripening their fruit, which is raiſed upon an elongated peduncle, and opens by four valves, filled with the ſeeds, attached to elaſtic cords. Theſe ſeeds have proved upon trial to reproduce their reſpective plants[*].

The genera comprehended under this ſubdiviſion of the Moſſes are, *Marchantia*, *Jungermannia*, *Targionia*, *Anthoceros*, *Blaſia*, *Riccia* and *Sphærocarpus*.

MUSHROOM. See *Agaricus*.

To what was ſet down under the article *Agaricus* reſpecting the culture of the Muſhroom, it may be uſeful to add the following practice from Juſtice's Britiſh Gardener's Director.

Make the beds at the end of auguſt, in order to furniſh the table with Muſhrooms all the winter, except in caſe of extreme and intenſe froſts.

Make the beds in the following manner: Dig a trench three feet wide, one foot deep, and what length you pleaſe (from ten to fifteen feet is ſufficient for a moderate family). If your ſoil be wetiſh, let the bed be quite above ground. Take horſe dung (three or four good cart-loads for twenty feet), lay it in a heap to ferment for ten or twelve days, or lay it abroad till little heat remains in it; for great heat deſtroys the ſpawn of Muſhrooms. The dung ſhould be warm and moiſt, not dry and ſuch as has already been exhauſted by fermentation. So ſoon as you perceive the heat to be gone off, fill the trench with the dung, near one foot above the ſurface of the adjacent ground; above that, lay ten inches of freſh, light, rich earth; and obſerve to cover the ſides of the dung-bed with the ſame earth, and as much of the earth gathered from the fields with the Muſhroom ſpawn upon the ſides, as can be; and then take ſome of the ſpawn, and plant the ſmall knobs of it ſix inches aſunder, half an inch deep into the earth: then take another layer of dung, lay it ten inches thick, and above that, another layer of the rich light earth, and the field earth on the ſides eight inches thick; obſerving as you lay the ſtratums of earth and dung, to draw in the ſides narrower, ſo as to make the bed aſcend gradually in form of a ridge, and ſtill drawing it narrower, till you arrive at the top, and in ſuch a manner, as the knobs of ſpawn may not be buried deeper than half an inch, planting the knobs all the way up; by which means you may have four layers of dung, and as many of earth.

When your bed is thus made and planted, lay good wheat-ſtraw, or looſe litter half a foot or more thick; and, as the cold increaſes, cover to twelve inches in thickneſs.

After ten days take off the litter with your hands, to ſee if the Muſhrooms begin to appear: if they come black or brown and long-ſhanked, cut them over, and riddle on a little of the fine earth upon them; and when they appear again, they will come up white, round and fit for uſe: this is called purging of them, their firſt bad appearance being owing to too much heat in the dung.

It will be neceſſary to look them over every day in ſeptember, which is the chief ſeaſon of their growth. If allowed to grow large, they will ſoon become too big for uſe, rot, breed worms, and infect all the young ſpawn near them. To prevent this, gather them once every day; in doing which, pull them gently out, ſo as not to leave their ſtems behind, which would canker and breed worms, and rot the ſpawn. If any of this ſhould come up with the Muſhrooms, take it off gently, and plant it in again without bruiſing it, and it will ſoon root. Make another bed in the ſame manner at the end of ſeptember, and no later.

Some make the Muſhroom-beds entirely of dung, without ſtratums of earth, only covering the ſides of the dung with earth, three or four inches thick. When this method is followed, always put good dry litter or ſtraw four inches thick between the earth laid on the ſides of the beds and the dung, which prevents the earth from caking or cracking into rents, which it is apt to do, from the heat of the dung: and on the top of the ſtraw, which immediately covers the Muſhroom-bed, put ſome warm litter from the ſtable, or from a dung-heap, in the cold ſeaſon; and this will much promote the growth of the Muſhrooms. If the froſt ſhould continue, and the warm litter cool, add ſome freſh warm litter upon the ſtraw-covering.

Such beds, if duly attended to, will laſt ſeveral months, and produce great crops; and as the Muſhrooms for uſe grow, ſo will the ſpawn, which ought to be laid up in a dry warm place until the ſeaſon for uſing it. The ſpawn will keep four months; ſo that if you give up the Muſhroom beds in may, the ſpawn will keep until ſeptember following, among their own earth, and even until october or november in a warm and dry place: auguſt however and ſeptember are the months for making muſhroom-beds.

In very ſevere froſts or great rains, obſerve to increaſe the ſtraw-coverings, and in great ſtorms ſometimes lay boards above the ſtraw, ſo as to reſt gently againſt the ſides of the beds, but not to reſt ſo much on the Muſhrooms as to bruiſe them.

By continuing the forcing of Muſhrooms, they may be continued good until the months of april or may. If when Muſhrooms are ſet down in auguſt, ſeptember or october, or even later, they do not produce immediately, they ſhould not be deſtroyed, but let them remain all winter covered with ſtraw, and in march probably, but moſt certainly in april, may and june, a moſt plentiful crop of Muſhrooms may be expected.

Another method of raiſing Muſhrooms is this—About the end of february lay old rotten dung in a trench nine inches deep, and ſix feet in breadth, fill it up and tread it well down, and above the dung put ſome earth, taken in october preceding from a paſture where Muſhrooms grow in plenty: cover the dung with it five inches thick, tread it as hard as you can, and make the bed level: keep it clear from weeds, and in may the Muſhrooms will begin to appear: if they come up black, take ſome turf of the Muſhroom paſture,

[*] Withering, 1. 363.

pasture, half an inch thick only, and tread it down on the bed; this will purge them, and make them come up of a good colour. Such a bed will continue good for two years.

Panicle with coloured leaves.

2. Mussænda glabra.

Vahl symb. 3. 38.

Branches and leaves of the branches and panicle very smooth.

3. Mussænda chinensis.

Lour. cochinch. 152.

Leaves in bundles, flowers solitary.

DESCRIPTIONS, &c.

1. This is a large woody climbing shrub, without tendrils or thorns, having many long scattered branches. Leaves ovate-lanceolate, quite entire, wrinkled, hairy, subsessile, opposite. Flowers gold-coloured, in large, spreading, terminating cymes, with large, ovate, nerved, very white, petioled bractes. Calyx tubular; segments awl-shaped, hairy, erect. Border of the corolla short; segments acute, tailed. Anthers erect. Style equal to the corolla. Stigmas lanceolate, erect. Berry ovate-oblong two-celled. Seeds roundish [a]. According to Gærtner, the Berry is inferior, ovate-globular or subturbinate, with a prominent whitish ring from the remains of the calyx, and within that, marked at the top with five minute tubercles, and on each side with an obscure longitudinal groove, smooth, black, two-celled: skin thin, becoming leathery when ripe: pulp watery, finally vanishing. Receptacle an ovate fungous lamina bent like an ox-yoke, and by means of another transverse lamina fixed on both sides to the middle of the partition, both together forming the Burgundian cross, as Rumphius calls it, in the middle of the fruit. Seeds very numerous, small, subovate, compressed like a lens, shagreened, pale.

Linneus remarks, that the panicle is dichotomous. One bractle of each pedicel grows into a white elliptic nerved leaf, longer than the panicle.

He gives Belilla of Rheede, and Folium principissæ of Rumphius as synonyms to his Mussænda frondosa. The first of these has oblong berries and black seeds: the second has almost cylindrical berries, excavated on the outside. Gærtner can scarce believe them all three to be one and the same species. He is certain however that his plant is the genuine Mussænda of the Ceyloneſe and of Hermann. Vahl suspects that Folium principissæ of Rumphius rather is the same with his Mussænda glabra. Loureiro remarks, that the figures and descriptions of Burmann and Rumphius agree in many things, but not in all, with his plant, and that they do not entirely agree with each other, but that the differences are rather those of varieties than species. In the Cochinchinese plant he did not observe any smell, but great beauty in the singular whiteness of the bractes mixed with the golden flowers; and it is remarkable that these bractes do not adhere to the peduncles, but to the fruit.

Native of the East Indies and Cochinchina, Otaheite and Namoka islands in the South Seas.

2. Branches round, purplish dotted with white, smooth. Leaves petioled, opposite, three inches long, attenuated, ovate, quite entire, smooth on both sides except on the rib underneath, obliquely and alternately nerved, obscurely veined. Stipules obliterated. Panicle terminating. Partial peduncles three or four times dichotomous, opposite, with a pedicelled flower at each of the divisions. Bractes under the ramifications, trifid as in M. frondosa, deciduous, but five times smaller; segments lanceolate, smooth. Bractes under the last pedicels lanceolate, quite entire, sometimes cut with a toothlet at top, scarcely villose. Flowers pedicelled; pedicels angular, the length of the germ. Segments of the calyx lanceolate, slightly hairy with minute hairs. Tube of the corolla pubescent, an inch long, thicker in the middle: segments of the border lanceolate, in the dry specimen orange above. Fruit smooth, obovate, umbilicate, obscurely marked with five lines. Leaves of the panicle three times as large and firmer than in M. frondosa, ovate, obtuse, marked with four larger nerves, vanishing towards the tip, smooth on both sides, yellowish underneath in the dry specimen, greenish above, decurrent a little at the base. It appears to be quite different from the preceding, in having the leaves smooth on both sides, and not as in that hoary underneath, with the bractes and calycine segments smaller; in the size, consistence and colour of the leaf of the panicle, and in its orange-coloured flowers.

The leaves of the panicle in M. frondosa are more tender, acuminate, acute not blunt, the segments of the calyx are longer, and the fruit villose, not smooth as in M. glabra, which is a native of the East Indies as well as the other [b].

3. This is a small tree, with diffused unarmed branches. Leaves lanceolate, quite entire, smooth, heaped. Flower terminating, with a berried, five-parted calyx, having lanceolate segments. Berry ovate, crowned, pale, four-celled; containing many, almost kidney-form, bony seeds.—Native of China, near Canton [c].

PIST. *Germ* ſhort. *Style* filiform. *Stigma* in the Hermaphrodites ſimple: in the Females two, briſtle-ſhaped.

PER. none.

SEEDS ſomewhat oblong. *Down* feathered.

REC. naked.

ESSENTIAL CHARACTER.

Cal. cylindric, imbricate. *Corollets* of the ray oval-oblong; of the diſk trifid. *Down* feathered. *Recept.* naked.

SPECIES.

1. Mutiſia Clematis.
Linn. ſuppl. 373. *ſyſt.* 769. *Gærtn. fruct.* 2. 454.

DESCRIPTION, *&c.*

This is a climbing plant, like Clematis, when young tomentoſe all over. Stem ſhrubby, ſtriated, long, branched, twining. Leaves alternate, remote, pinnate; with the rachis ending in a tendril. Leaflets oblong-ovate, ſubſeſſile, alternate or oppoſite, ſeven, by age becoming ſmooth above, but very tomentoſe underneath. Stipules in pairs, ovate, many times ſmaller than the leaflets. Peduncles axillary, ſolitary, one-flowered, tomentoſe, with one or two ſmall awl-ſhaped bractes. Flowers the ſize and form of a large Pink. Calyx tomentoſe. Corolla purple, the length of the ray of the calyx itſelf. It was found in New Granada by Mutis*.

Juſſieu remarks, that it has the calyx of Scorzonera; and, independent of the flower, the habit of Vicia. Joſeph de Juſſieu had given it the Peruvian name *Cunirima*; and it is allied on one ſide to *Cheiriraga*, and on the other to *Barnadeſia*.

MYAOIDES. See *Draba*.

MYAORO SIMILIS. See *Eryſimum* and *Myagrum*.]

MYAGRUM, (*of Pliny*, Μυαγρος *of Dioſcorides: from* μυια, *a fly, and* αγρευω, *to catch.*)

Silicles angular, leaves three-parted.

DESCRIPTIONS, *&c.*

Under this genus are assembled by Linneus—1. Myagrum T. with a turbinate compressed three-celled silicle, not opening, the two upper cells empty, the lower one-seeded. 2. Camelina Dod. with a pear-shaped, two-celled, two-valved, many-seeded silicle. Moenchia With. Alyssoides T. and Veficaria T. now added to Alyssum, are perhaps congeners with this. 3. Rapistrum T. with a silicle either oblong and two-jointed, or spherical acuminate two-celled, one joint or cell empty: the other one-seeded scarcely opening. Lamarck adds to these Anastatica syriaca, and most of the species of Bunias, with a spherical or four-cornered fruit, and some Sisymbriums with a short pod (Radicula of Haller) two-celled and many-seeded. He refers Myagrum saxatile to Cochlearia, on account of its ovate, two-celled, many-seeded fruit. In such a confusion of species it is scarcely possible to define the genus, and it might perhaps be better to divide them, and restore some of the old genera[a]. These reformations may be made without end in orders so natural as this, wherein all the species may be considered as forming one great genus, in which the subordinate divisions are generally arbitrary.]

1. Mr. Miller, though he gives this plant Linneus's epithet of *perenne*, describes it as an annual plant; the lower leaves large jagged and hairy; the stalks branching out from the bottom; the leaves about four inches long, and two broad, hairy and unequally jagged; the stalks terminated by very long loose spikes of yellow flowers, succeeded by short pods with two joints, each including one roundish seed.

[Linneus remarks, that the lower joint of the silicle is strict and abortive; the upper globular, striated, one-seeded.

Scopoli describes the stem as grooved, branched, firm and somewhat villose; the leaves pinnatifid, the pinnas toothed here and there, the terminating one very large and roundish; the upper leaves lanceolate, toothed: the flowers in long spikes; petals yellow, twice as long as the calyx: the fruiting-peduncules more remote, pressed close to the stem: the first joint of the silicle more slender and less villose; the upper one ovate, and striated longitudinally: there is an evident partition, but it is loose at the sides, or at least does not cohere every where with the inner surface of the valves.

M. perenne of Miller, Scopoli, Gerard, &c. is probably different from that of Linneus. Miller says it is annual, and Gerard that it is biennial. Villars mentions a perennial sort which he has seen cultivated, with an enormous root, of a lower stature, and a smaller smooth fruit.

Native of Germany. Cultivated in 1739 by Mr. Miller[b], if this be his plant.

2. This is an annual plant. The silicles have two joints, with three ridges, and a style the length of the silicle. Native of the Levant[c].]

3. This also is an annual plant, the lower leaves of which are five or six inches long; they are hairy and succulent, their base is eared, and they end in acute points. The stalks are a foot and half high, brittle and hairy, branching out toward the top, and terminated by short loose spikes of small pale flowers; which are succeeded by small rough roundish capsules, compressed at the top.

[Villars describes his Myagrum rugosum, which he makes synonymous with M. perenne of Scopoli and Miller, thus: Stem a foot high, a little villose, very much branched at the base. Leaves a little rough, sinuated, lyrate, or deeply cut like those of *Sinapis arvensis*: the upper ones are narrower and almost entire. Calyx green, shorter by half than the petals; which are pale yellow, wide, rather large: there are two green pointed glands between the two longer stamens and the calyx. Silicle short, seeming to be two-celled, but the lower part is smaller, square, one-celled, often barren: the upper part is channelled and villose, terminated by the style, which is longer than the silicle. Seeds a little lengthened out. It is biennial. Native of the South of Europe.

Allione makes his Rapistrum rugosum synonymous with Myagrum rugosum of Linneus and Villars, and describes it thus. Stems round green hispid, from half a yard to three quarters of a yard in height, branching from the very bottom, the branches subdivided, each horizontal or reclining, flowering to a great length. Root-leaves on a semicylindric petiole, pinnatifid, pinnas triangular, gradually larger, the extreme one largest, the first and second pinnas scarcely toothed; they are rough with stiffish hairs, succulent and of an acid flavour. Leaves on the stem only one at the base of each branch; the lower ones have one or two pairs of pinnas, the next one only, the rest are almost entire and linear. Flowers in very long racemes. Calyx spreading, of a very pale yellowish green colour, the leaflets concave and linear. Petals ovate, entire or slightly emarginate, sulphur-coloured. Stamens a little higher than the stigma. Filaments tinged with purple. Anthers grooved, linear. Germ a little hirsute. Style longer than the calyx. Stigma headed, bifid. Silicle ovate, not opening, hirsute, with wrinkled interrupted ribs on it, one-celled. Seed one ovate a little compressed shining; and sometimes there is another little joint.

4. Stem rugged with scattered reflex hairs. Racemes rod-like, long. Leaves lyrate, toothed, petioled, oblong. Silicles cylindric, even, not grooved, wrinkled or striated, consisting of an oblong, pedicelled, cylindric, barren body, upon which an ovate silicle is placed with a narrower neck; the lower joint is two-celled and empty, the upper has one seed in it. Corolla yellow. It is a biennial plant, native of Spain[a].

5. The whole plant is smooth: the stems subangular, herbaceous, erect, branchy, leafy, and about a foot or a cubit high. Leaves oblong, obtuse or a little acute, the radical ones attenuated at the base and notched: those on the stem sessile, embracing the stem with their produced bases, and of a sagittated form, with serrated edges. Flowers yellow, on corymbose terminal racemes stretching gradually to two or three inches. Germ globose and smooth. Style thick and short, ending in a headed obtuse stigma. Silicle globose, small, crowned by the obtuse style, obscurely footstalked, smooth, equal, two-celled, with about five subovate seeds on each side, fixed to the dissepiment. This species grows in clayey ground, and flowers in June. Native of Austria[a].]

6. This has a smooth branching stalk upwards of two feet high. The lower leaves are five or six inches long, smooth, succulent, and a little indented; the upper leaves almost embrace the stalks with their base. The flowers are produced in long loose spikes, are yellow and sessile.

[Villars describes the plant as about a foot in height, with straight stems and very spreading branches; the leaves smooth, with a tinge of ash-colour on them; the lower ones sinuated or waved, the upper ones entire. The whole plant is smooth. The flowers small. The silicle obcordate, three-celled; the two upper cells, which are lateral, are empty, and the lower one, which answers to the axis, is filled with a single seed.

Mr. Miller says, the pod is heart-shaped and compressed, divided by a longitudinal partition into two cells, each containing one roundish seed. [The accurate Gærtner describes it as spongy-tuberous, oblong, terminated by the tubulate style; the upper part twin-globular, two-celled, barren; the lower cylindric or obconic, one-celled, fertile; both parts are valvulets and never open. Seed ovate-oblong, with a streak along the middle on each side, rust-coloured, fattened by a short umbilical chord descending from the top of

[a] Jacquin. [b] Hort. kew. [c] Linn. [a] Linn.

the lower cell.—It differs from *Crambe* in having flat cotyledons or seed-lobes, not conceave-conduplicate, as in that genus.

It is an annual plant, native of the South of France and Switzerland. Mr. Miller adds Italy.—Cultivated in 1658, in the botanic garden at Oxford. It flowers in june and july[1].]

7. This is an annual plant, with an upright ſtalk about a foot and half high, ſending out two or four ſide branches towards the top, which grow erect; they are ſmooth and have a fungous pith: the lower leaves are from three to four inches long, of a pale or yellowiſh green, and eared at the baſe; thoſe upon the ſtalks diminiſh in ſize all the way up, are entire and almoſt embrace the ſtalk with their baſe. The flowers grow in looſe ſpikes at the end of the branches, ſtanding upon ſhortſtalks an inch long. Petals ſmall, yellowiſh. Silicles oval, bordered, crowned with the ſtyle, two-celled; the cells filled with red ſeeds.

[Lower part of the ſtem round, upper ſomewhat angular, ſlightly hairy. Leaves cloathing the whole ſtem, alternate, lanceolate, arrow-ſhaped at the baſe, half-embracing, ſlightly toothed, hairy. Flowers yellow. Silicles on long fruitſtalks, terminated by a long ſtyle: the partition extends beyond, and forms a ſtrong ridge round the ſilicle[2].—Linnæus remarks, that the capſule or ſilicle bellies out on each ſide, but is uſually, in the wild plant, marked with a cavity preſſed inwards, which cavity diſappears in the cultivated plant[3].

Villars obſerves, that the ſtem has only one or two branches, and is ſometimes quite ſimple. Pollich, that the flowers are almoſt three lines in diameter; the petals blunt but quite entire, pale yellow, with claws two lines and a half long; two glands or nectaries at the ſhorter filaments; germ ſmooth, ſtyle yellowiſh green, ſtigma yellowiſh: ſilicle wider at top, terminated by the ſtyle of the ſame length with itſelf, and having five, ſix or ſeven ſeeds in each cell.

According to Cavanilles, the whole plant is very villoſe; the leaves very ſoft; the root-leaves oblong, blunt, ſubſpatulate; the ſtem-leaves ſeſſile, alternate, half-embracing, having blunt ears; the upper ones very ſharp and much ciliated. Flowers in terminating racemes; each flower on a ſmooth pedunele, three times as long as the fruit.

It is cultivated in Germany for the ſake of the expreſſed oil of the ſeeds, which is there uſed for medicinal, culinary and œconomical purpoſes. The ſeeds are a favourite food with geeſe, horſes, kine, ſheep and goats eat it[4].

Native of Germany and the ſouthern countries of Europe, in corn fields, and eſpecially flax, with the ſeed of which it has been introduced into the more northern parts, as Sweden, Denmark and Britain. With us it has been found near Bridport and Lime in Dorſetſhire; Heydon in Norfolk.] Mr. Miller found it growing in the corn in Eaſthamſted Park, the ſeat of William Trumbull, Eſq.

Following Tournefort, he makes two ſpecies of this, under the names of M. ſativum (n. 1.) and Alyſſum (n. 2.). The latter, he ſays, differs from the former in having a taller ſtalk; the leaves are much longer, narrower, and regularly indented on their edges, ending in obtuſe points. The flowers are larger, but of the ſame form and colour. The capſules are much larger, and ſhaped like a heart.

[β. Has the leaves ſmooth and more green.

γ. Is a remarkable variety, every where ſmooth; the lower leaves are laciniated and pinnatifid; the reſt are toothletted. The ſmell is not very fetid. Silicle many-ſeeded[5].

8. Root ſmall, annual, fuſiform, white within and without, four inches long. Stem erect, two feet high and more, ſomewhat angular and rugged, having one or two alternate branches at the upper part; both terminated by a looſe longiſh raceme, with the flowers on round peduncles, three or four lines in length. Leaves alternate, ſagittate or rather eared, embracing, hirſute on both ſides, the lower four inches long, and an inch wide. Corolla ſmall, yellow; petals wider at top and blunt, a little more than a line in length. Silicle very ſmall, orbicular, rugged, obſcurely wrinkled, crowned with the ſtyle, containing one ſeed[6].

Native of Europe. Introduced in 1787, by Mr. Zier. It flowers in july and auguſt[7].

9. Root perennial, long, brown. Root-leaves many, ſpread out in a ring, oblanceolate, (turbiculate, or oblong) gradually attenuated into the petiole, blunt, unequally obſcurely and thinly toothed, thickiſh, ſlightly rough, leſs than an inch in length, deep green. Stem ſlender, ſmooth, half a foot or a ſpan in height, upright, round, hard, ſimple, having a few ſcattered ſublinear leaves on it, broadiſh at the tip; and terminated by a corymbed many-flowered raceme, either ſimple, or compounded of a few axillary liliform racemes. Calyx yellowiſh white. Petals white, ſpreading very much, twice as long as the calyx, roundiſh. Style ſhort. Silicles almoſt globular[8]. The ſtamens are differently deſcribed: according to Jacquin, the longer filaments are contiguous and forked at top, the inner diviſion being truncated, the outer arched outwards; the ſhorter ſtamens have a gland on each ſide. In Krocker's ſpecimen the filaments were ſimple. Villars remarks, that the lateral filaments are elbowed outwards, and as it were broken at a right angle, without being forked.

There ſeem to be ſeveral varieties of this ſpecies. Linnæus mentions three plants which were ſent him, one by Allione, and two by Seguier, on which he does not poſitively determine whether they are diſtinct ſpecies, or only varieties of this.

The firſt from Allione has the root-leaves ſpatulate, rugged, bluntiſh, quite entire; the ſtem-leaves tongue-ſhaped and ſmoothiſh; the ſtem ſimple.

The ſecond from Seguier has the root-leaves as in the firſt, and the ſtem-leaves tongue-ſhaped, but ſagittate at the baſe; the ſtem has a few racemes.

The third, alſo from Seguier, has the root-leaves lanceolate, ſomewhat toothed, rugged; the ſtem-leaves lanceolate, ſomewhat toothed, ſubpetioled; the ſtem with a few racemes.

Villars mentions two varieties; one drawn by Plumier at the Grande Chartreuſe; Alyſſon alpinum of Scopoli, n. 793. with the lower leaves roundiſh and hirſute; they are more numerous, and it has ſeveral on the ſtems: another, with the root-leaves ſeſſile, lanceolate, toothed, thick, gray from the quantity of ſimple hairs that cover it, and having ſome reſemblance to Draba alpina of Linnæus.

Native of the mountains of France, Italy, Auſtria and Switzerland. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in june and july[9].

10. Stem divaricated, with rod-like racemes. Leaves petioled, three-parted or five-parted, toothed. Capſules or ſilicles have two four-cornered joints. Flowers yellow. Style very ſhort. It has the appearance of Bunias Cakile.—Found in Egypt by Haſſelquiſt[10].]

PROPAGATION AND CULTURE.

If the ſeeds of theſe plants are permitted to ſcatter in the autumn, the plants will riſe without any care, and only require to be thinned and kept clean. Theſe autumnal plants will always ripen their ſeeds, whereas thoſe which are ſown in the ſpring ſometimes fail.

Leaves elliptic crenulate subcoriaceous, stigmas two to four sessile.

DESCRIPTION, *&c.*

1. This is an upright shrub, divided into few branches, on sandy shores three feet high, in woods eight feet. Root thick, knobbed, irregular; the bark brown without, orange within: the wood solid, whitish, very bitter. Leaves ovate or lanceolate, acute, very finely serrate, on very short red petioles, opposite but sometimes alternate. Peduncles filiform, axillary, opposite, bifid; each division trifid and three-flowered; the middle flower opening long before the side ones. Flowers small, of a dark shining red. Fruit red, soft, the size of peas. The Spaniards call it *Yerva de maravedi*.

At Carthagena they use a decoction or infusion of the root as a powerful diuretic: the leaves have the same quality in a much smaller degree. It is abundant about Carthagena in New Spain, and in the island of St. Martin, in places not far from the sea[t].

2. This is an upright branching shrub, from two to three feet in height, with an ash-coloured bark. Branches subdivided, even, strict. Leaves small, half an inch in length, opposite, stiffish, scarcely nerved, smooth, somewhat shining, on very short petioles. Flowers in small racemes, very minute, red. Racemelets or peduncles two or three-flowered, axillary, shorter than the leaves. Calyx four-cleft, very shortly tubular, coloured red at bottom. Corolla deeply four-parted subrotate, whitish red; segments ovate, minute, fringed at the edge. Filaments from the base of the corolla between the segments of it, bent in above the tube. Anthers simple, very minute. Germ ovate. Style awl-shaped, the length of the tube of the corolla. Stigma four-cleft. Drupe roundish, the size of a small red currant, scarlet, shining, containing a spherical one-seeded nut.

Native of Jamaica, on the western sandy coasts; flowering in summer. In habit it resembles the preceding, but has smaller, ovate leaves, and an undivided style.

3. This is a branching shrub, three or four feet in height. Branches scattered, four-cornered, smooth. Leaves opposite, oblong, blunt, remotely notched, veined, very smooth, rigid, on short petioles. Peduncles shorter than the leaves, axillary, few-flowered: pedicels one-flowered. Flowers very small, whitish. Corolla with a very short tube: border spreading, four-parted; parts oblong, blunt, flat, reflex, entire. Filaments in the divisions of the corolla, the length of the border. Anthers roundish. Germ globular. Style none. Stigmas sessile, globular. Drupe globular, containing an oblong, bony, wrinkled nut[u].

The branches are round at bottom and ash-coloured; the younger ones green, opposite, four-cornered. Leaves sessile, opposite and alternate, an inch long, often roundish, with simple veins, smooth on both sides. Peduncles solitary, filiform, trifid: pedicels somewhat branched. Fruit obovate, smooth, nearly the size of Pepper, hanging down.

Native of the West Indies.

MYOPORUM. (*Myoporos ευρυς, Pori obstructi, obstructed pores. The plant appearing as if scattered over with points or pores filled up with a pellucid substance.*)
Soland. Forst. prodr. 44. *Lin. gen. Schreb. n.* 1053.
Class. 14. 2. Didynamia Angiospermia.
Nat. order of *Perfonatæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted: *segments* ovate, acute, erect, permanent.
COR. one-petalled, bell-shaped: *border* spreading, almost equal, five-parted.
STAM. *Filaments* four, two shorter. *Anthers*
PIST. *Germ* oblong, compressed. *Style*
PER. *Berry* one-celled.
SEEDS one or two, two-celled.

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* bell-shaped, with a spreading almost equal five-parted border. *Berry* one or two-seeded. *Seeds* two-celled.

SPECIES.

1. Myoporum laetum.
Forst. prodr. n. 238.
Leaves oblong, subserrate at the tip, even, smooth, shining, corollas hirsute.
2. Myoporum pubescens.
Forst. prodr. n. 239.
Leaves oblong-elliptic serrate pubescent.
3. Myoporum crassifolium.
Forst. prodr. n. 240.
Leaves oblong subserrate fleshy.
4. Myoporum tenuifolium.
Forst. prodr. n. 241.
Leaves lanceolate acuminate quite entire, corollas smooth and even.

These plants are natives of the islands of the South Sea. The first and second of New Zealand; the third of Botany island; and the fourth of New Caledonia.)

DESCRIPTIONS, *&c.*

1. Hairy Mouſe-ear Scorpion-graſs has an annual fibrous root. Stems ſeveral, procumbent aſcending or erect, according to circumſtances, a long ſpan or a foot in height, or even ſomewhat more in moiſt ſituations or ſtrong land, angular, villoſe, branching towards the top for flowering: branches axillary, alternate. Leaves alternate, quite entire, bent back a little at the edge, having no apparent veins, but a very ſtrong rib along the back, which makes a ſhallow channel along the upper ſurface, of a light green colour, villoſe on both ſides and along the edge, and ſomewhat rugged: the lower leaves are elliptic or oblong, blunt, running down into the petiole, three inches long, and ſometimes more, meaſured from the ſtem; the middle and upper ones are lanceolate, tharpiſh, ſeſſile or half embracing, from an inch and half to two inches in length; both are half an inch or five lines in width. Flowers in racemes, whilſt young bending in at the top, whence the names of *Scorpioides*, *Scorpiurus* and *Scorpion-graſs*, from the ſimilitude to a Scorpion's tail; as the flowering advances, lengthening out very conſiderably and divaricating: they are alternate, in a double row, and all grow one way, each on its proper pedicel. Calyx villoſe, deeply five-cleft, cloſing at top as the ſeeds ripen. Corolla red before it opens, but when open of a fine blue, with a yellow eye, not more than a tenth or a twelfth of an inch in diameter.

The above deſcription was made on the 2d of june, 1798, from plants growing wild in a garden, in hedges, and by a brook.

This plant varies much according to the ſoil and ſituation in which it grows. On barren paſtures, heaths and walls, the plant and flowers are both much ſmaller. I have ſeen it ſcarcely more than an inch in height, bearing one minute flower only.

Merret mentions two varieties: one with wider leaves, very hairy, and larger flowers, appearing earlier than the common ſort; this grows in woods only, and owes its ſuperior ſize probably to its damp ſhaded ſituation. It was obſerved by Mr. James Sherard on the weſt of Charlton-wood, and between Redgwell and Bathampend (or Bathon-inn) in Eſſex by Mr. Dale, and is figured in Dillenius's edition of Ray's ſynopſis: the other ſmall, rough-haired, with yellow flowers, appearing in april, and occurring in very dry ſandy paſtures; in ſuch a ſoil the blue border of the corolla is very ſmall, and ſometimes is ſcarcely expanded, ſo that it appears to be wholly yellow.

β. Haller, who ſeparates the *paluſtris* from the preceding, ſays that the root is larger, long, black and perennial, the ſtem higher, the leaves larger, the flower much larger and of a paler colour. He makes Merret's firſt variety to be a variety of this: and this is what Curtis ſeems to have figured for the *paluſtris*, for the plant in his figure is very hairy, which the true paluſtris is not. According to him, the root runs out to a great length through the water, and ſends down fibres from the joints. Stalk creeping at bottom, afterwards upright, from one to two feet high, round, ſolid, branched, ſmooth, but often hairy. Leaves alternate, lanceolate, ſeſſile, ſlightly decurrent, ſmooth or hirſute, the edge often rolled back. Racemes long, dichotomous, divaricating, the tops rolled in. Flowers pedunculed and growing all one way; peduncles alternate, upright. They are much larger than thoſe of the other, are remarkable for their beauty and delicacy, ſomewhat reſemble blue enamel, and are a very pretty ornament for the edges of ponds.

Lees.

Leers thus diſtinguiſhes them: *arvenſis* has a fibrous, annual root; ſtem branched; leaves hirſute; calyx deeply five-cleft, cloſing as the ſeed ripens: ſheep do not eat the plant: *paluſtris* has a creeping perennial root; ſtem ſomewhat branched; leaves ſmooth; calyx a little open even when the ſeed is ripe: it is noxious and even deadly to ſheep.—This notion of *Myoſotis paluſtris* being deadly to ſheep is derived from Linnæus, and I very much ſuſpect that it is erroneous, it has this bad character in common with many other aquatic plants (Droſera, Pinguicula, Hydrocotyle, &c), which I believe ſheep never eat.

Withering ſays that M. arvenſis is a ſmaller plant than M. paluſtris, and the bloſſoms much ſmaller; the latter obſervation is generally juſt, but the rough Scorpion-graſs is frequently as large a plant as the ſmooth, when it grows in moiſt ſhady places.

It appears to me that M. arvenſis is villoſe or very hairy with ſmaller flowers in all ſoils and ſituations: M. paluſtris is ſmooth with larger, paler flowers, moſt exquiſitely elegant. It ſeems to flower later; for whilſt I am writing this article at the beginning of june, M. arvenſis is in full flower, and ſome of it even going off, and I cannot find a ſingle ſpecimen of M. paluſtris in flower, to compare with it.

I firſt diſcovered M. paluſtris in flower on the 11th of june. The root is truly repent. The whole plant is of a much paler green. The ſtem is ſomewhat hairy, but ſcarce viſibly ſo except towards the top. The leaves are all lanceolate, none of them ſo broad at the baſe as in the arvenſis, and I cannot diſcover any hairs on them. The corolla is four times as large as the largeſt of arvenſis, being more than three eighths of an inch in diameter, of an elegant pale blue like ſmalt, with a large deep yellow eye.

Allione and Villars have another variety, which they have adopted as a ſpecies from Haller, and he from Scheuchzer and Segnier, and have named M. nana. It is a very low plant, not even three inches in height, with a very thick tuft of leaves. Leaves roundiſh, like thoſe of Thymus Serpyllum, ſubhirſute. Spike ſmall, few-flowered, ſeldom many more than three; but a ſingle flower occupies the whole, being large and of a very bright blue colour. Calyx bearded with a long ſilky pile[a].

It forms ſolid tufts on the higheſt precipices. Leaves ſmall, blunt, lanuginous. Stems ſometimes only a line, and never more than two inches in height. It is perennial and common on the Alps[b]. Villars inſiſts that this is a diſtinct ſpecies; but ſituation changes this plant ſo much, that I ſuſpect it to be no more than a variety.

2. Stem a foot high, woody, perennial, even. Branches many, flowering at the top. Leaves alternate, linear, almoſt even, with a few hairs preſſed cloſe. Spikes terminating, with the flowers pointing one way, not peduncled. Flowers and fruits minute. Native of the Cape of Good Hope[c].

3. This is an annual plant. Leaves large. Seeds naked on the inſide, angular, erect, fixed at the baſe as in the following ſpecies. Fruit nodding.—Native of Virginia[d]. Cultivated by Mr. Miller in 1768.

4. This alſo is annual. Stem from nine or ten inches to eighteen inches in height, erect, round, ſomewhat rugged. Branches alternate. Leaves ſeſſile, ſomewhat rugged, very narrow, quite entire, blunt iſh. Flowers very ſmall, not from the axils, but on the ſide oppoſite to the leaf, at the branches, on ſhort peduncles. Corolla bright blue. Calyx open when the ſeed is ripe[e]. Seeds ſmall, coriaceous, ovate-acuminate, ſhagreened all over with bony pointed dots, on one ſide convex and muricated at the ſides with a double row of hooked prickles, angular on the other[f].

Gærtner calls theſe fruits nuts, the ſeed being covered with a ſhell. With reſpect to this genus he remarks, that it is too artificial, and differs not, in any eſſential point, from Cynoglosſum. This remark, might with equal juſtice be made on many other genera in claſſes ſtrictly natural. Villars alſo obſerves, that this little plant has all the port or air of a Cynoglosſum.

Native of many parts of Europe: Sweden, Denmark, Germany, France, Switzerland, Italy.—It was cultivated in 1683, by Mr. James Sutherland, and flowers from april to auguſt[g].

5. Stems woody at the baſe, diffuſed, dichotomouſly branched at top, cloſely hairy, aſh-coloured, as is the whole plant. Leaves ſeſſile, blunt iſh, ſpreading a little at the end. Peduncles on the branchlets, axillary, ſolitary, remote, ſhort: two leaflets under each calyx. Flowers ſmall, white. Fruit pyramidal, muricated all over, ſpiny-angular at the baſe with larger tubercles. Seeds or nuts ſhining, compreſſed at the ſides, acuminate, keeled, keel toothed[h].

6. Root reddiſh, annual. Stems ſimple or branched, a ſpan high. Leaves ovate, ſoft, ciliate, villoſe, ſeſſile, the lower ones embracing. Flowers in terminating racemes, recurved at the end. Calyx whitiſh with pubeſcence, ſwelling at the baſe, deeply five-parted; ſegments converging, acute. Corolla deep ſulphur-coloured, funnel-form: tube longer than the calyx, priſmatic at the baſe: border ſpreading very much, five-parted; ſegments orbiculate, quite entire; ſealelets roundiſh. Seeds ovate[i].

On account of the ſituation of the ſtamens, and the integrity of the petals, Cavanilles removes this ſpecies into the genus Anchuſa, where Lobel had placed it before. He ſuggeſts alſo that Myoſotis and Anchuſa might very well conſtitute one genus. To this ſuggeſtion may be applied the remark made above, under the fourth ſpecies.

Native of the South of Europe: France, Spain, Italy: alſo of Japan, where it flowers in april: about Madrid it flowers in march: with us in june and july. Cultivated by Mr. Miller in 1768[k].]

7. Native of New Zealand[l].

PROPAGATION AND CULTURE.

Sow the ſeeds in autumn, upon an open bed or border of light earth. In the ſpring thin the plants where they are too cloſe, and keep them clean. Or if the ſeeds be permitted to ſcatter, the plants will riſe without farther trouble.

[MYOSOTIS. See *Ceraſtium* and *Stellaria*.]

MYOSURUS. (*Mouſe tail.*)

[*Lin. gen. n.* 394. *Reich. n.* 426. *Schreb.* 538. *Gærtn. t.* 74. *Juſſ.* 253. Myoſuros *Dill. gen.* 4.

Claſſ. 5. 7. Pentandria Polygynia.

Nat. order of *Multiſiliquæ*. *Ranunculaceæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* half-lanceolate, obtuſe, reflex, annexed above the baſe, coloured, deciduous.

COR. *Petals* five, ſhorter than the calyx, very minute, tubular at the baſe, opening obliquely inwards: (with a nectariferous pore at the claws. *G.*)

STAM. *Filaments* five or more (five to twelve. *G.*), the length of the calyx. *Anthers* oblong, erect.

PIST. *Germs* numerous, placed on the receptacle in a conic-oblong form. *Styles* none. *Stigmas* ſimple.

PER. none. *Receptacle* very long, ſtyle-ſhaped, covered with the ſeeds diſpoſed imbricately.

SEEDS very numerous, oblong, acuminate.

OBS. *The number of ſtamens varies much. It bears a near affinity to* Ranunculus. *What are called petals here, in Syſt. veg. are ſaid to be awl-ſhaped petal-like nectaries. The ridges in the ſeed ſeems to be the ſtyle adhering longitudinally to the germ.*

ESSENTIAL CHARACTER.

Cal. five-leaved, growing together at the baſe. *Pet.* five, (or *Neſt.* five, awl-ſhaped, reſembling petals, and) having a melliferous pore at the claw. *Seeds* numerous (five to twelve.)

DESCRIPTION, &c.]

This plant is very near a-kin to Ranunculus, in which genus it was ranged by Tournefort. The flowers are extremely small, and are succeeded by long slender spikes of seeds, resembling the tail of a mouse, whence it had the name.

[Root annual. Leaves all radical, about twenty in a plant of a middling size, upright, of unequal lengths, linear, broadest at top, flattened, faintly channelled on each side, smooth, somewhat fleshy, blunt, of a yellowish green colour, and reddish at the base: sometimes hairy, according to Hudson. Scapes or flowering stems four, five or more, each supporting one flower, upright, from two to four inches in height, longer than the leaves, round, smooth, a little thicker at the top. Calycine leaflets concave, herbaceous, with the claws lengthened out behind, pressed to the flowering stem, and tapering to a point. Petals of a yellowish colour*. Stamens varying in number from four or five to ten, twelve and even twenty, according to different authors.—Seeds compressed wedge-shaped; the outer side ferruginous, linear-lanceolate, with a ridge along the middle; the other sides half-ovate, flat, blackish, converging into a very acute angle*.

Mr. Curtis remarks, that the structure of the whole fructification, in this delicate little annual plant, is singular, and deserving the attention of the young botanist, who should be careful to distinguish the corolla from the stamens.

It grows wild in most parts of Europe, Linneus says on dry open hills; with us I have commonly found it by the sides of corn fields, especially where water has stagnated in winter, and this year (1798) coming up as a weed in a garden. Dr. Withering assigns it to corn fields, meadows and pastures in a gravelly soil.] Mr. Miller says it grows wild upon moist ground. It has occurred to me generally among clay. In English Botany it is said to be a native of gravelly corn-fields. That elegant and interesting work, describes the pistil to be conical, longer than the stamens, composed of a conical receptacle, covered with a great number (even two or three hundred) of ovate striated germs, each furnished with its own minute sessile stigma.

This plant affords a rare instance of a very great disproportion of males to females in the same flower, and yet the latter are generally all prolific. The seeds are justly described by Linneus as naked, for the part which Jussieu (and Gærtner) call a capsule is nothing more than a thickened inseparable coat, as in Ranunculus, to which Myosurus has a great affinity in its nectariferous pore.

A plant which I have before me, and which grew in a garden on a good soil, has above fifty scapes of very different lengths, some above seven inches and others about three inches long: the leaves three inches and a half in length; I do not perceive any trace of hairiness on them. It flowers in april and may, and and is not disposed yet to shed its seeds on the seventh of june.]

MYRICA. (*of Pliny, Marrien of Theophrastus and Dioscorides. Derivation merely conjectural, ἀπὸ τοῦ μυρίζω, either because it grows near streams, or because it is fabled that the daughter of Cinyras was changed into* this plant: *this verb signifying both* thus *and* lugeo. *It was put as a wreath round the heads of criminals, and the wood was accounted unfortunate.*)

Class. 22. 4. Dioecia Tetrandria.

Nat. order of *Amentaceæ*, Lin. Juss. &c.

GENERIC CHARACTER.

* *Male.*

CAL. *Ament* ovate-oblong, imbricate on all sides, loose, composed of one-flowered, crescent-shaped, bluntly acuminate, concave *scales*. *Perianth proper* none.

COR. none.

STAM. *Filaments* four (seldom six) filiform, short, erect. *Anthers* large, twin, with bifid lobes.

* *Female.*

CAL. as in the male.

COR. none.

PIST. *Germ* subovate. *Styles* two filiform, longer than the calyx. *Stigmas* simple.

PER. *Berry* one-celled.

SEED single.

OBS. *There is a great affinity between this genus and Fothergilla.* M. Gale *has four stamens, and a dry berry, or leathery case, compressed at top and three-lobed.* M. cerifera *has usually six stamens, and a succulent globular berry.—Calyx three or four-leaved: stamens four or six: style one bifid: fruit a drupe,* Gærtn.

ESSENTIAL CHARACTER.

Ament with a crescent-shaped scale. *Cor.* none.

FEM. *Styles* two. *Berry* one-seeded.

DESCRIPTIONS, *&c.*

1. This riſes with many ſhrubby ſtalks from two to near four feet high, dividing into ſeveral ſlender branches, [and covered with a duſky or ruſt-coloured bark, ſprinkled with white dots. The buds are compoſed of nine leafy ſhining ſcales, the firſt nearly oppoſite, very ſhort, rectangularly pointed, the reſt ovate, blunt.] Leaves alternate, ſtiff, an inch and half long, and half an inch broad in the middle, light or yellowiſh green, ſmooth, a little ſerrate towards their points, and emitting a fragrant odour when bruiſed: [this is occaſioned by the reſinous points with which they are ſprinkled: they are convoluted and petioled. The flowers appear before the leaves; and the flower-buds are above the leaf-buds, at the ends of the branches, whence as ſoon as the fructification is completed the end of the branch dies, the leaf-buds which are on the ſides ſhoot out, and the ſtems become compound. The aments or catkins are of a ſhort ovate figure, of a yellowiſh brown colour, and frequently ſprinkled with ſhining reſinous golden particles. The fruit is a coriaceous berry. The male and female aments are ſometimes on diſtinct plants, and ſometimes on the ſame individual[a]. Dr. Withering affirms that he has found a few female flowers upon the male catkins. Mr. John Templeton, of Orange Grove, near Belfaſt, informs me that the monoecous plants may be diſtinguiſhed by the form of the leaves being exactly lanceolate, the broadeſt part lying in the middle; whereas in the dioecous plants the broadeſt part is near the apex, and the leaves in general are much ſmaller.

The leaves have a bitter taſte, and an agreeable odour, like thoſe of Myrtle. Their eſſential oil riſes in diſtillation. The northern nations formerly uſed this plant inſtead of Hops, and it is ſtill in uſe for that purpoſe in ſome of the weſtern iſles and a few places of the highlands of Scotland. Unleſs it be boiled a long time, it is reported to occaſion head-ache. The catkins or cones boiled in water throw up a ſcum reſembling bees-wax, which gathered in ſufficient quantity would make candles. From the next ſpecies Myrtle candles are prepared in America. It is uſed to tan calf-ſkins. Gathered in the autumn it dies wool yellow, and is uſed for that purpoſe both in Sweden and Wales. The Swedes ſometimes uſe a ſtrong

[a] Linn. Iap. & ſpec. Lightf. Stokes in Wither.

decoction of it to kill bugs and lice, and to cure the itch. The Welſh lay branches of it upon and under their beds to keep off fleas and moths, and give it as a vermifuge in powder and infuſion, applying it alſo externally to the abdomen. In moſt of the Hebrides, as well as in the Highlands of Scotland, an infuſion of the leaves is frequently given to children to deſtroy worms. In Iſla and Jura the inhabitants garniſh their diſhes with it, and lay it between their linen and other garments, to give them a fine ſcent, and to drive away moths. When it grows within reach of a port, the ſailors make beſoms of it for ſweeping their ſhips. In the iſle of Ely they make faggots with it to heat their ovens.

Linnæus was induced to ſuſpect, from the ſmell of this ſhrub, that Camphor might poſſibly be prepared from it. Horſes and goats eat it; ſheep and cows refuſe it[b].

Native of the northern parts of Europe, and of North America, in bogs: flowering with us in may. Not unfrequent in many parts of England, Wales, Scotland and Ireland, [particularly in the northern and weſtern counties, alſo in Windſor-park and near Tunbridge-wells; [in the fens of the iſle of Ely; about Wareham in Dorſetſhire, between Shap and Anna Well in Weſtmorland. Gerarde ſays, it grows by Colbrooke, and in ſundry other places. Darlingham-moor, in Norfolk. Frequent in the Highlands of Scotland.

In England it has the names of Sweet Gale, Goule, Gaule, Sweet Willow, Wild Myrtle and Dutch Myrtle. The Scotch call it Gaul; and the Iriſh Moſs-Gaul. Our Gaul is from the German and Dutch *Gagel*. In thoſe languages, as well as in the Daniſh and Swediſh, it is alſo called *Port* or *Poſt*. In French it is, *le Gale odorant, le Piment royal, Myrthe bâtard* or *du Brabant, Piment des marais*.

So little was the Tea ſhrub known formerly, that Simon Paulli aſſerted it to be the ſame with our Sweet Gale.

2. American Candleberry Myrtle is a ſhrub, or a tree acquiring a height of thirty feet: the bark is warted; the branches unequal and ſtraight. Leaves evergreen, ſomewhat cluſtered, blunt at the end, membraneaceous-rigid, wrinkled, ſmooth, covered underneath with very minute, ſhining, orange-coloured, glandular pores. Flowers in aments, on different individuals. Swartz had not an opportunity of obſerving the male aments.] Miller ſays they are about an inch long, and ſtand erect. [The female aments are ſeſſile, axillary, linear, ſhorter than the leaves. Scales very minute, and between each of them an oblong minute germ, longer than the ſcales; two filiform ſtyles, the length of the germ; and reflex ſtigmas. Berry minute, roundiſh, yellow[c]. Gærtner, finding the ripe fruit to be farinaceous, as Miller and Kalm had deſcribed it, calls it a Drupe; which is juiceleſs, ſuperior, ſmall, ovate-globular, defended at the baſe by the four calycine leaflets, acuminate above, covered all over with a white farinaceous ſubſtance mixed with many hard duſky granules, making the whole of the rind in the ripe fruit: ſhell ovate-acuminate, bony, thickiſh, one-celled, valveleſs. Seed filling the cavity of the ſhell, pale yellow with duſky veins, and a white ſcar at the baſe[d].]

Willich remarks, that he finds ſometimes four, and ſometimes ſix ſtamens[e].]

Mr. Miller makes two ſpecies of this. The Common ſort, according to him, riſes with many ſtrong ſhrubby ſtalks eight or ten feet high, ſending out many branches. Leaves ſtiff, near three inches long, and one inch broad in the middle, ſmooth, entire, of a yellowiſh lucid green on their upper ſide, but paler on their under, alternate, ſubſeſſile, having a grateful odour, when bruiſed. Male and female flowers on different plants. Male catkins about an inch long, erect. The female flowers come out on the ſide of the branches in longiſh bunches; and are ſucceeded by ſmall roundiſh berries, covered with a ſort of meal.

[b] Withering. Lightf. Linnæus. [c] Swartz. [d] Gærtner. [e] Obſ. 6.

The Broad-leaved American Candleberry Myrtle; *Myrica caroliniensis* as he names it, does not rise so high as the former, the branches are not so strong, and they have a grayish bark. The leaves are shorter, broader, and serrate. In other respects it is like the preceding, and the berries are collected for the same purpose.

[They are natives of North America: and of Jamaica, in the highest mountains. The common sort was cultivated in 1699, by the Dutchess of Beaufort. They flower in may and june [1].

Candles are made from the berries in North America, whence it is called there the *Tallow shrub* or *Candleberry tree*; some also name it the *Bayberry-bush*. It grows abundantly on a wet soil, and seems to thrive particularly well in the neighbourhood of the sea, nor does it seem ever to be found high up in the country. The berries intended for making candles are gathered late in autumn, and are thrown in a pot of boiling water; their fat melts out, floats at the top of the water, and may be skimmed off. The fat when congealed looks like tallow or wax, but has a dirty green colour; it is therefore melted again and refined, by which means it acquires a fine and pretty transparent green colour. It is dearer than common tallow, but cheaper than wax. They usually mix some tallow with it. Candles of this kind do not easily bend or melt in summer, as common candles do; they burn better and slower, nor do they cause any smoak, but rather yield an agreeable smell, when they are extinguished. At present not many candles of this kind are used, the animal tallow is readily come at, it being very troublesome to gather the berries. They are chiefly used by poor people, who live near where the bushes grow, and have not cattle enough to supply them. A soap is made from the fat, which has an agreeable scent, and is excellent for shaving: and it is used by surgeons for plaisters. In Carolina they likewise make sealing-wax from these berries. The root is accounted a specific in the tooth-ache [2].

3. Native of Madeira and the Azores, where it was found by Mr. Francis Masson. Introduced in 1777. It flowers in june and july [3].

4. This is an obscure shrub, approaching to M. Gale and cerifera. Leaves alternate, petioled, coriaceous, naked, having three or four teeth on each side. Spikes axillary, erect, shorter by half than the leaf.—Native of the Cape of Good Hope [4].

5. This is a shrub, with round, smooth branches. Leaves subpetioled, an inch long, narrow-lanceolate, attenuated to both ends, smooth, having five or six minute sharp approximating serratures towards the tip. Flowers glomerate in a sessile head, axillary, small, smooth. Calyx four-leaved: leaflets minute, lanceolate. Filaments scarcely any. Anthers four, longer than the calyx. Berry the size of a pepper-corn. It has the habit and fruit of Myrica, but differs from it in having a four-leaved calyx, in the same manner as the next species, which Gaertner has distinguished under the name of Nageia [5].

6. Stem shrubby, smooth, upright. Branches decussated, round, knobbed, spreading very much, leafy. Leaves cliptic, sessile, blunttish, oblique, smooth and even, opposite, spreading, leathery, a finger's length. Berry globular, smooth, the size of a Cherry [6].

Calyx two-leaved or four-leaved. Fruit a superior, spherical, berried drupe, dark-purple with a bloom or meal on it, when ripe: rind fleshy, succulent, moderately thick: shell spherical, with an acuminate point at top, bony, thin, brittle, one-celled, valveless. Seed of the same shape with the cavity, tuberculated, fixed by the top [7].—Native of Japan.]

7. Stalks slender, shrubby, about four feet high, dividing into smaller branches. Leaves about an inch and half long, and almost an inch broad, some of them having two, others three deep opposite indentures on their sides, they sit close to the branches, and end in obtuse indented points: between the leaves come out some oval catkins, which drop off. This species retains its leaves all the year.

[1] Hort. kew. [2] Kalm. [3] Hort. kew. [4] Linn. mant. [5] Vahl. [6] Thunberg. [7] Gaertner.

[Mr. Miller had not an opportunity of observing the female flowers or the fruit. Mr. Ray mentions that the fruit is dry when ripe, and contains only a single seed.

Mr. Miller makes two species of this—M. quercifolia and hirsuta.] The first having smooth shining stalks and leaves, both of which are hairy in the second, and the leaves of a darker green. He received them from Holland as different species, but he suspected them to be what they certainly are, mere varieties.

Native of the Cape of Good Hope. [Cultivated in 1752 by Mr. Miller. It flowers in june and july [8].]

8. This has a weak shrubby stalk, five or six feet high, sending out many long slender branches, closely garnished their whole length with small heart-shaped leaves, sitting close to the branches, slightly indented and waved on their edges. The flowers come out between the leaves in roundish bunches: they have an uncertain number of stamens, and are all included in one common scaly involucre or cover. The leaves continue all the year green.

[Mr. Miller had not an opportunity of observing the female flowers.

Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1759 [9].

9. This is a shrub, with alternate petioled leaves; leaflets sessile, lanceolate, acuminate, tomentose underneath. Fruits in a raceme, berried, rugged.—Native of the Cape of Good Hope [10].]

PROPAGATION AND CULTURE.

1. The first sort growing naturally in bogs, cannot be cultivated in a garden without bog earth in a moist situation.

2. American Candleberry Myrtle is propagated by seeds sown in autumn; for if they are kept out of the ground till the spring, they seldom grow till the year after. The plants require water in dry weather, and should be screened from frost whilst young. When they have obtained strength, they will resist the cold of this country very well. This shrub delights in a moist soft soil.

4. 7, 8, 9. As these do not produce seeds here, they are propagated by layers, but they do not take root very freely, so that the plants are not very common in Europe; for I do not find that the cuttings of these plants will easily take root, having made several trials of them in all the different methods; nor have the Dutch gardeners had better success, so that the plants are as scarce there as in England.

When the layers are laid down, that part of the shoot which is laid should be tongued at a joint, as is practised in laying Carnations; and the young shoots only should be chosen for this purpole, for the old branches will not put out roots. These layers are often two years before they will have taken root enough to transplant, for they should not be separated from the old plants till they have made good roots, because they are very subject to miscarry if they are not well rooted.

When they are taken off from the old plants, they should be each put into a separate small pot, filled with soft, rich, loamy earth; and if they are placed under a common frame, shading them from the sun in the middle of the day, it will forward their taking new root; then they may be placed in a sheltered situation during the summer, and in the autumn removed into the green-house, and treated in the same way as other plants from the same country. The best season for laying down the branches, I have observed to be in july, and by the same time the following year they have been fit to remove.

Flowers in leafy whorls.

DESCRIPTIONS, &c.

Theſe are perennial herbs, inhabitants of the water. Leaves in whorls, pinnate, linear. Flowers axillary, ſeſſile, ſolitary, in the upper whorls male, in the lower female. In the ſecond ſpecies they are frequently hermaphrodite [a]. Juſſieu has placed theſe plants among the *Acotyledones*; they belong however clearly to the *Dicotyledones*, for the two lobes of the ſeed are much more eaſily diſcerned and ſeparated than in Calliriche [b].

1. Stem branched. Leaves in whorls under water, pinnate; pinnas capillary, deep green. Flowering ſpike riſing above the water, bearing ſix or eight whorls of ſeſſile flowers; the upper male, ſomewhat crowded, the lower female, more diſtant. Calycine leaflets oval, concave, purpliſh on the outſide, ſoon deciduous. Anthers yellowiſh green. Calyx of the female flowers ſmaller. Stigmas ſpreading, cruciform [c].

[a] Juſſieu. [b] Gærtner. [c] Woodw. Mſ.

Gmelin obſerves, that there are always four leaves in a whorl; Pollich that there are four, ſix, and even more; that four ſeſſile flowers make a whorl, that there are eight, nine, or ten whorls in a ſpike, the four uppermoſt of which have male flowers.

Withering remarks, that the ſtems are reddiſh, divided within into about ſixteen cells, and that ſome of the males contain the rudiments of four germs.

Profeſſor John Martyn, in a M. S. note in the margin of Ray's hiſtory, deſcribes the flowers as having four petals, with a ſmall four-parted calyx, both ſitting on the germ; the petals very fugacious, falling as ſoon as they open, and diſcovering the anthers on very ſlender filaments in the male flowers; ſoon after the calyx alſo falls off, and diſcovers the four-cleft ſtyle in the female flowers.

Gærtner names the ſeeds nuts; ſometimes there are two of theſe, but more frequently four; they are ſmall, ſubglobular, before they are ripe united by means of the rind, but afterwards ſeparable: rind thin, membranaceous: ſhells hard, ſomewhat bony, thick, whitiſh, one-celled. Seeds ſolitary, ſubcylindric, pale.

Native of moſt parts of Europe, in ſtill water, as ditches, ponds and lakes. It flowers from may to july.

3. More branched: ſpikes ſmaller: broadiſh entire leaves at the baſe of the whorls.—Found by Bobart near Lodden-bridge, not far from Reading; alſo in the river on Hounſlow-heath [a].

2. In muddy ditches with little water, the ſtems ſimple, ſix or eight inches high. Leaves not more than an inch long, with pinnas one and a half or two lines in length. In ponds the ſtems branch, and are two feet or more in length; the leaves under water one and a half or two inches long, with ſlender capillary pinnas. Spike ſix or ſeven inches long, with from twelve to ſixteen whorls or more, the lower ones about half an inch diſtant, the upper ones nearer, with four or five pinnate leaves at each whorl, about half an inch long, the pinnas about a line in length. Flowers in the axils of the leaves ſimilar to thoſe of the preceding: the flowers of the upper whorls are uſually male, thoſe of the lower female; ſometimes the upper are male, the middle hermaphrodite, and the lower female [b].

Linnæus ſays that he has ſeen plants with male and female flowers diſtinct, and that he has alſo ſeen it with hermaphrodite flowers, but not ſo frequently. According to Turra, the flowers are hermaphrodite, and the leaves in fours.

Villars obſerves that the leaves of this are leſs fine and diſtinct than thoſe of the firſt ſort; that the flowers come out among theſe, inſtead of being ſeparate: and that the ſtems do not ſtand ſo high out of the water.

This alſo is an inhabitant of ditches and ſtagnant waters, but not found ſo extenſively as the other, and leſs common in Britain. With us it has been obſerved in two or three places near Cambridge; by the bridge on the Botley road, near the lane going to Medley, in Oxfordſhire, near Bungay, in Suffolk; near Yarmouth and at Hedenham, in Norfolk; and in the river near Peterborough. It flowers in june and july.

DESCRIPTIONS, *&c.*

1. The Nutmeg is a large tree, with erect branches, and a smooth ash-coloured bark; the inner bark is red. Leaves petioled, alternate, quite entire, shining, paler underneath, nerved. Peduncles axillary, two or three-flowered, solitary; but only one flower arrives at maturity. Calyx fleshy, smooth, segments spreading, shorter than the tube. Filament solid, the length of the calyx. Anthers eight, ten or twelve, growing longitudinally round the upper half of the filament. Calyx in the female smaller. Covering of the fruit (or mace) subdivided irregularly somewhat like a net, fulvous. The leaves are aromatic; and if the trunk or branches be wounded they yield a glutinous red liquor*.

Linnæus was not acquainted with the true character of the Nutmeg-tree, and it is imperfectly described in the *Supplementum Plantarum*, from a specimen sent by Sonnerat. The fructification was first accurately described by Thunberg in the Stockholm acts for 1782: and afterwards by Swartz, from specimens preserved in spirits in the collection of Sir Joseph Banks, which came from Banda and the Isle of France.

Gærtner has described the fructification thus:

Flowers of distinct sexes on the same trunk. Calyx trifid, in the female inferior. Corolla none. Stamen one, thick: anthers sessile at top. Style one. Fruit a superior berry, elliptic-spheroidal, with a shallow longitudinal groove on one side, fleshy, very smooth, one-celled: flesh thick, rather solid, finally drying up into a coriaceous crust, opening on the side. Seed one, ovate-globular, nucamentaceous, arilled, by help of this aril fixed to the bottom of the cell. The aril or cover, which is commonly called *Mace*, is fleshy-coriaceous, reddish saffron-coloured or yellow, one-leafed at bottom, multifid at top; the segments linear, flexuose, branched, widening upwards and sometimes gashed at the top. Integument double: the *outer*, a thin brittle shell, pale chestnut-coloured, shining, reticulated by the impressions of the aril: the *inner* membranaceous-cruftaceous, subrufescent, very closely cleaving to the kernel, and deeply immersed in its substance, by its internal processes. Albumen of the same form with the seed, fleshy-farinaceous, as it were chewed, variegated whitish and bay, having a cavity at bottom for the embryo, and sometimes a void space in the middle, fragrant and gratefully aromatic. Embryo small, erect, hollowed out like a dish, milk-white: cotyledons fleshy-foliaceous, waved, from upright spreading into a two-parted almost hemispherical cup, joined. Radicle inferior, in form of a very small tubercle, under the cotyledons. The fruit would be a drupe, were it not for the Aril.

* Swartz.

The Nutmeg-tree is a native of the East Indies, and especially of the island of Banda, in latitude 4° 30′ S. longitude 128° 10′ E.—It has in a manner been extirpated in all the islands except Banda, which might easily supply every nation upon earth; it is however certain that there a few trees of this spice upon the coast of New Guinea. There may perhaps be both Cloves and Nutmegs upon other islands to the eastward; for those neither the Dutch nor any other Europeans seem to think it worth while to examine*.

* Cook's voy. 744.

Monf. Poivre sent persons in june 1770 to the least frequented part of the Moluccas in search of what the avarice of the Dutch had hitherto withheld from the rest of the world; and to him the French Colonies in the isles of France and Bourbon are indebted for the Nutmeg, Clove and Cinnamon.

By an account sent to Monf. de Sartines in 1779, by the King of France's gardener at the island Bourbon, it appears that the King's garden there possessed at that time thirty-eight male aromatic Nutmeg-trees, and eight female, the produce of two importations. The first female, produced by the nuts of the first importation, bore six Nutmegs the preceding year. These were all of the long form, and surrounded by the Mace on all sides. Since that time a second and third female tree, produced by the nuts of the last exportation, have yielded nuts of the same long shape. A fourth tree shew nuts, which were very large, and likely to be of the long sort. A fifth yielded nuts one-third smaller: the Mace went only half round them, leaving them at liberty to break from it: they were round, and had a longitudinal stripe on one side.

The gardener relates that he had twenty-nine Nutmeg-trees in his orchard, of which two only were female; the case is the same in other plantations, and all these males came from long nuts planted in 1772.

It being probable that the woods in the Moluccа islands produce more of the trees which bear long nuts, than of those which bear round ones, the natives probably gave the former, and the merchants took them without suspecting any fraud. It might therefore have happened, that not a single fruiting tree of the true sort had been imported; and in fact, there was not one fruiting tree of the first importation any where but in the King's garden, and that produced long nuts. So that had not Monf. Poivre sent a second time to the Moluccas, the French colonies might never have had a second female tree.

The gardener distinguishes the trees into three sorts. The Male or barren Nutmeg. The Royal Nutmeg, or female producing the long nuts. And the Queen Nutmeg, yielding the precious round nuts, intended to reproduce the females, but which gives separately, the one long nuts intended to give males, the other round nuts intended to produce the two sorts of females; namely, that producing the long, and that producing the round nut.

The only difference between the Royal and Queen Nutmeg is in the fruit. That of the Royal is thicker, longer and more pointed, the green shell is thicker, and it is longer in ripening: the green shell, after opening, preserves its freshness eight or nine days: the

Mace is more ſubſtantial, and three or four times as long as that of the Queen Nutmeg; and its ſtripes or thongs, of which there are from fifteen to ſeventeen principal ones, are of a livelier red; they are alſo broader, longer and thicker, and not only embrace the nut throughout its whole length, but paſs it and croſs under it, as if to hinder it from falling. The Royal Nutmeg is generally from fifteen to ſixteen lines long, thick in proportion, and has no longitudinal ſtripe. It remains on the tree a long time after the opening of the green ſhell, and gives birth to inſects in the ſhell that feed upon it.

The Queen Nutmeg produces much ſmaller nuts, only nine or ten lines long, not ſo thick by a third, and well marked by a longitudinal groove on one ſide; they are round and reſemble a ſmall Peach: the green ſhell is not thick: the Mace, which is compoſed of nine or ten principal ſtripes, grows only half down the nut, leaving it at liberty to eſcape and plant itſelf. By thus detaching itſelf, the nut prevents the inſects from deſtroying it: the green ſhell alſo, changing at the end of two or three days, ſoon falls, and ſeparates from the nut. This green ſhell, when preſerved, has the fine taſte of the nut itſelf[c].

A ſmall eſtabliſhment for theſe ſpices has alſo been formed by the French ſince 1769, on the iſle of Secheyles, in latitude 4° 38' S.[d]

The Nutmeg-tree has been introduced into the Britiſh territories in the Eaſt Indies. Captain W. C. Lennon of the Mary, acquaints Dr. Anderſon, at Madras, on the 20th of auguſt, 1796, that he had brought ſafe from Amboyna and Banda, ſome Clove and Nutmeg plants of the beſt kinds, and that it was chiefly owing to Captain Oſborne of the Centurion, that he was enabled to bring them in ſafety to Pulo Penang. He had on board ſeven Nutmeg and four Clove trees, of which two of the former were planted at Madras, the reſt were ſent to Marmalon, excepting two of the Nutmeg trees, which had been forwarded by Captain Pakenham for Mr. Andrew Roſs.

A premium has been offered by the Society of Arts, Manufactures and Commerce of London, ever ſince the year 1783, for the greateſt quantity of merchantable Nutmegs, not leſs than five pounds weight, the growth of our iſlands in the Weſt Indies; but hitherto without ſucceſs.

Sir George Staunton relates, that a perſon belonging to the Embaſſy to China had a preſent from the medical garden at Batavia of a young growing Nutmeg plant, and of a nut ſuppoſed capable of germination; that he committed them to the care of a gentleman bound for England, in order to be put in his Majeſty's botanic garden at Kew; but that the Nutmeg-plant ſuffered in the paſſage, and was left at St. Helena.

Sir George ſays that the Nutmeg-tree, with a ſmooth brown bark, riſes perfectly ſtraight. Its ſtrong and numerous branches proceed regularly in an oblique direction upwards. They bear large oval leaves pendulous from them, ſome a foot in length; the upper ſurface ſmooth and of a deep agreeable green; the under ſurface marked with a ſtrong nerve along the middle, from which others proceed obliquely, it is of a uniform bright brown colour, as if ſtrewed all over with a fine brown powder, and the whole leaf is very fragrant[e].

2. A tree of forty or ſixty feet high; branching at the top: the branches long, tortuous, upright and declining; ſcattered here and there: the leafy and flowering branchlets downy and ferruginous: the leaves cordate-oblong, ſharp, green above, and ſmooth; below downy, and reddiſh: they are perfectly entire and have ſhort footſtalks: the flowers are borne in cluſters and are axillary and terminal: the raceme is large, downy, and ferruginous. The flowers heaped, five or ſix, ſeſſile. The fruit varies in ſize and form on different trees; being twice as large in ſome: it is oblong, the valves being produced into an obtuſe cylinder. From the kernel is extracted a ſpecies of yellowiſh ſuet or fat, which ſerves for various medical and œconomical purpoſes; and is made into candles. From the wounded bark flows a red acrid juice.

Native of marſhy woods and hills in Guiana[f].

3. Native of Tobago.

The number of anthers in the firſt ſpecies is ſcarcely to be diſtinguiſhed, being aſſimilated by the polliniferous grooves, and not having three more diſtinct as in this and *ſobifera*. Aublet has figured his *Virola* with ſix ſtamens, which muſt be a miſtake, as appears from the ſpecimens, which have been carefully examined by Swartz.

Gærtner has given three other ſpecies of Myriſtica:

1. Myriſtica dactyloides. 195. *t.* 41. *f.* 2.
M. fructu inodoro. *Lin. zeyl. n.* 588.
Nux indica oblonga, intrinſecus ſimilis nuci moſchatæ. *Bauh. hiſt.* 1. 399.
Panam-Palca. *Rheed. mal.* 4. 9. *t.* 5.
Nux moſchata malabarica. *Valent. muſ.* 1. *epiſt. orient.* 83. *t.* 4.
N. myriſtica major ſpuria malabarica. *Raij hiſt.* 1524.
Berry ovate oblong, yelloviſh green, with a fleſhy ſoft thick rind. Mace like that of the true Nutmeg in ſhape and colour, but not ſo pleaſant in taſte and ſmell. Shell of the ſame ſhape with the ſeed, of a black bay colour. Seed without ſmell, ovate-cylindric, aſh-coloured or dirty reddiſh, variouſly wrinkled, convex on one ſide, and marked with a groove on the other. Albumen farinaceous, may be grated like ſuet, inſipid, and has a large cavity for the embryo a little above the baſe. Embryo largiſh, concave: corydedons fleſhy-foliaceous, from upright ſpreading, with the edges fringed, plaited and channelled.—Native of Malabar and Ceylon.

2. Myriſtica Irya. *Gærtn.* 195. *t.* 41. *f.* 3.
Iria Iryaghas. *Lin. zeyl. n.* 589.
Nux zeylanica, moſchatæ rotundæ ſimilis, inodora minor. *Herm. muſ.* 49. *Burm. zeyl.* 172.
Shell globular, depreſſed a little, cruſtaceous, thin, brittle, dirty white, marked with ſuperficial capillary veſſels, regular, not wrinkled. Seed globular, wrinkled with tubercles, brown bay. Albumen void of ſcent, of a white ſuety ſubſtance, that may be grated, appearing as if it had been chewed by the reddiſh-bay proceſſes of the integument, and having a very void ſpace in the middle. Embryo at the bottom of this cavity, ſmall, greeniſh: cotyledons ovate, fleſhy-foliaceous, flattiſh, from horizontal ſpreading, radicle conical, inferior.—Native of Ceylon.

3. Myriſtica Iriaghedhi. *Gærtn.* 196. *t.* 41. *f.* 4.
Iriaghedi. *Lin. zeyl. n.* 590.
Nux moſchata ſpuria, quæ pſeudo nux moſchata zeylanica. *Herm. muſ.* 58.
N. moſch. ſp. ſylveſtris, caryophylli arboris fol. oppoſitis. *Burm. zeyl.* 173. *t.* 79.
Shell ovate-oblong, very like the preceding in its whole ſtructure. Seed of the ſame ſhape with the ſhell, deeply ſtriated and wrinkled, brick-coloured, when it is moiſtened, of a bright vermilion. Albumen very much ruminated or chewed, elegantly variegated with white and red, having no ſmell: the white part is ſuety and may be grated; the red is branny and friable. Embryo like the preceding.—Native of Ceylon.

PROPAGATION AND CULTURE.

The Nutmeg-tree not having been yet introduced among us, we cannot give any particular directions for the ſtove culture of it. In its native ſoil, it grows in woods, and ſeems to be propagated by birds. We have no inſtruction for the culture of it in the Eaſt or Weſt Indies, where it has been introduced, farther than what we are told by the French gardener in iſle Bourbon: that what he calls the Royal and Queen Nutmegs are the only trees that always bear, and conſequently the only ones to be planted; and that their produce is as ſure as if they were hermaphrodite trees. The kernel of the firſt will produce only a male or barren tree; but the nut of the latter will always produce a fruitful one. So that if planters have one hundred Queen Nutmegs, and one Royal one, they will be ſure of having one hundred fruiting trees, and one

male

male tree to fecundate them. Without attending to this, they might have had a great quantity of male trees to a ſmall quantity of females; and they would not have diſcovered the miſtake till after five or ſix years, when the trees came to flower.

MYRMECIA. (*Μυρμηκια is an Ant's neſt.*)
Lin. gen. Schreb. n. 177. Tachia. *Aubl. guian.* 75. *t.* 29. *Juſſ.* 142.
Claſſ. 4. 1. Tetrandria Monogynia.
Nat. order of *Gentianæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed; tubular, long, five-toothed: toothlets erect, acute.
COR. one-petalled: *tube* long: *opening* inflated: *border* five-cleft; ſegments ovate, acute, revolute.
Nectary five ſmall glands ſurrounding the baſe of the germ.
STAM. *Filaments* four, filiform, inſerted at bottom into the tube, and longer than it. *Anthers* linear, erect.
PIST. *Germ* oblong, ſuperior. *Style* filiform, longer than the ſtamens. *Stigma* bilamellate.
PER. *Capſule* long, two-celled, two-valved, covered by the permanent calyx.
SEEDS numerous, very ſmall, viſcid, adhering to the partition.

ESSENTIAL CHARACTER.

Cal. tubular, five-toothed. *Cor.* one-petalled, with an inflated mouth, and five-cleft border. *Germ* with five glands at the baſe. *Stigma* bilamellate. *Capſ.* two-celled, two-valved, many-ſeeded.

SPECIES.

1. Myrmecia Tachia.
Lin. ſyſt. ed. Gmel. 247.
Tachia. *Aubl. guian.* 75. *t.* 29.

DESCRIPTION, *&c.*

This is a ſhrub with a trunk of five or ſix feet in height, thick at the baſe, and gradually diminiſhing as it aſcends: it throws out here and there long, rough, four-cornered branches, which are oppoſite and tubular: at each knot of theſe branches grow two oppoſite leaves diſpoſed croſſways: they are ovate, ſharp, perfectly entire, ſmooth, ſubſeſſile, and embrace the ſtem. From the boſom of one or other of theſe leaves proceeds a ſeſſile flower, of a yellow colour. It generally happens that at the boſoms of thoſe leaves which do not produce flowers a tear of yellow reſin makes its appearance. The hollow trunk and branches of this ſhrub are commonly the retreat of a great many ants, for which reaſon it is called by the natives by the name of Tachi, which is ſaid to ſignify an ant's-neſt.

MYROBALANUS. See *Phyllanthus* and *Spondias*.
MYROBATINDUM. See *Lantana*.
MYRODENDRUM. (*Μυρον μυρου ointment, and δενδρον a tree.*)
Lin. gen. Schreb. n. 901. Houmiria. *Juſſ.* 435.
Houmiri. *Aubl. guian.* 564. *t.* 225.
Claſſ. 13. 1. Polyandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-toothed, acute.
COR. *Petals* five, oblong, acute, ſpreading, much larger than the calyx.
STAM. *Filaments* twenty, capillary, inſerted into the receptacle. *Anthers* roundiſh.
PIST. *Germ* roundiſh, ſmall, ſuperior. *Style* long, curved inwards, villoſe. *Stigma* capitate, five-lobed.
PER. five-celled.
SEEDS ſolitary.

ESSENTIAL CHARACTER.

Cor. five-petalled, ſpreading, much larger than the five-toothed calyx. *Stigma* capitate, five-lobed. *Per.* five-celled, with one ſeed in each cell.

SPECIES.

1. Myrodendrum balſamiferum.
Lin. ſyſt. ed. Gmel. 817.
Houmiri balſamifera. *Aubl. guian.* 564. *t.* 225.

DESCRIPTION, *&c.*

A tree of fifty or ſixty feet high, and two feet in diameter. The bark thick, reddiſh, and rough: the wood hard and brown: it throws out from the top ſeveral large branches, which divide into branchlets beſet with alternate, entire, ſmooth, green, firm, long leaves, terminating in a point. Theſe leaves are largeſt at their baſe, where they partly embrace the branchlets: the young leaves are reddiſh: thoſe of the young trees are ſix inches long, and two broad. The flowers are borne in heads or cluſters from the boſoms of the leaves at the extremities of the branchlets, and are of a white colour.

The bark of this tree affords a red balſamic fluid reſembling Styrax in ſcent: this liquor after it has exuded from the bark becomes hard, brittle, and tranſparent; and when burnt affords a very agreeable odour. The negroes and the natives of Guiana uſe the bark for the purpoſe of ſtips to make flambeaux. The natives alſo uſe the wood in building their houſes. The tree is called Red-wood by the Creoles, and by others is called Houmiri, and Touri. It grows in the foreſts of Guiana. The reſin, according to Aublet, might be uſed medicinally in the ſame manner as the Balſam of Peru.

MYRODIA. (*Unguentorum odor. From μυρον, and οζω, to ſmell. Smelling of perfumes.*)
Lin. gen. Schreb. n. 1147. *Swartz prodr.* 102. Quararibea. *Aubl. t.* 278. *Cavan. diſſ.* 3. 175. *t.* 71. *f.* 2. *Juſſ.* 274.
Claſſ. 16. 1. Monadelphia Polyandria.
Nat. order of *Columniferæ*. *Malvaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate-urceolate, coriaceous, toothleſs, burſting at top into unequal teeth, permanent.
COR. *Petals* five, inſerted into the receptacle, narrower below, oblong, oblique, blunt, from ſpreading recurved, longer than the calyx.
STAM. *Filaments* uniting into a long ſlender tube, widening at top, plaited-five-toothed, ſheathing the ſtyle. *Anthers* nine to fourteen, kidney-form, cluſtered towards the top of the tube, ſeſſile.
PIST. *Germ* ovate, in the baſe of the calyx. *Style* filiform, thickened at top, plaited, a little longer than the filaments. *Stigma* large, capitate or two-lobed.
PER. *Drupe* ſubglobular, dry, ſtipaceous, with a retuſe top, umbilicate with the remains of the ſtyle, two-celled or three-celled.
SEEDS ſolitary, angular on one ſide, convex on the other.

ESSENTIAL CHARACTER.

Cal. ſingle, one-leafed. *Cor.* five-petalled. *Piſt.* one. *Column* of anthers undivided. *Drupe* dry, incloſing two nuts.

SPECIES.

1. Myrodia turbinata.
Swartz prodr. 102.
Leaves elliptic, calyxes turbinate ſomewhat ſilky within.
2. Myrodia longiflora.
Swartz prodr. 103.
Quararibea guianenſis. *Aubl. guian.* 692. *t.* 278. *Cavan. diſſ.* 3. 175. *t.* 71. *f.* 2.
Leaves oblong, calyxes cylindric villoſe within, column of ſtamens very long.

DESCRIPTIONS, *&c.*

1. Native of the Weſt Indies, as Monſerrat, St. Lucia and St. Chriſtophers. The anthers are fourteen in number.

2. This is a ſhrub about ſix feet high, with a trunk of three or four inches in diameter; the bark is grayiſh and chapped: the wood white and of a ſlight texture: the ſhrub emits long, ſtraight, flexible, divided branches, garniſhed with ſmooth, alternate, green, entire, ſmooth, weak leaves: their footſtalk is ſhort, ſwoln, cylindric, and accompanied by two ſtipules which fall off ſoon: the largeſt leaves are about nine inches long, and three broad. The flowers ſpring from the boſom of the leaves, or even from the footſtalks themſelves, and are three, four or five in number: theſe footſtalks are often marked with ſmall greeniſh ſcales. The flowers are white. It is a native of Guiana, and grows on the banks of rivers, flowering in may.

MYROSMA. (*Μυρος οσμη, the ſmell of perfume.*)
Lin. gen. Schreb. n. 6. *Juſſ.* 63.
Claſſ. 1. 1. Monandria Monogynia.
Nat. order of *Scitaminæ*. *Cannæ*, Juſſ.

GENERIC

GENERIC CHARACTER.

CAL. *Perianth* superior double: *outer* three-leaved: *leaflets* equal, membranaceous, oblong, channelled, quite entire: *inner* three-parted; *segments* equal, spreading, oblong, quite entire, with a dusky spot at the top.

COR. one-petalled, unequal: *tube* very short; *border* five-parted; the two upper segments shorter, oblong, unequally emarginate; the three lower longer, trifid at the top and gashed; the middle one shorter.

STAM. *Filament* one, free or growing to the margin of the middle division of the lower segment of the corolla, membranaceous at the base, awl-shaped. *Anther* ovate, compressed.

PIST. *Germ* three-sided, inferior. *Style* thick, bent down, short, three-cornered, cloven longitudinally, hirsute before. *Stigma* open, with the lip dilated.

PER. *Capsule* three-celled, three-valved, three-cornered.

SEEDS several, angular.

ESSENTIAL CHARACTER.

Cal. double: outer three-leaved, inner three-parted. *Cor.* five-parted, irregular. *Caps.* three-cornered, three-celled, many-seeded.

SPECIES.

1. Myrospma cannæformis.
Lin. suppl. 80. *syst.* 51. *ed. Willd.* 13.

DESCRIPTION, *&c.*

This is a shrub growing like the Canna. Root horizontal, ascending obliquely at top, fleshy, ovate, short, slightly compressed as in Amomum, girt with rings, covered with alternate, embracing, ovate, appressed, broad, fibrous sheaths. Leaves oval, smooth, veined; the lower one with elongated, dilated, radicate petioles, forming the stem; the upper ones with petioles out of the stem. The petioles thus elongated become slender, compressed, channelled longitudinally, but towards the insertion of the leaf they are elevated into a cylindrical ring, hairy in front, curving the leaf inwards a little. Stems or scapes round, somewhat hairy, ending in a joint, whence springs a leaf very like the stem-leaves, and a peduncle involved in the sheath of the petiole. Peduncle solitary, scarcely longer than the petiole, round. Raceme like the ament of a Hop, imbricate with the alternate scales of the bractes. Bractes two-leaved, two-flowered: outer leaf wider, ovate, membranaceous, embracing; inner shorter, narrower, oblong[a].

This genus is allied to *Physurus* (Pontederia ovata), but it differs in the fruit[b].

Native of Surinam.

MYROSPERMUM. See *Myroxylum*.

MYROXYLON. Forst. See *Xylosma*.

MYROXYLUM. (*From μυρον, and ξυλον wood. Scent-wood.*)
Lin. suppl. 34. *Lin. gen. Schreb. n.* 709.
Myospermum. *Jacqu. amer.* 120. *Juss.* 365.
Class. 10. 1. Decandria Monogynia.
Nat. order of *Lomentaceæ. Leguminosæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-shaped, five-toothed, permanent, with very small obsolete teeth.

COR. *Petals* five, unequal, inserted into the receptacle; the uppermost wide, ovate, obcordate, reflex; the rest narrow-lanceolate, straight, scarcely spreading: *claws* narrow, linear, the length of the calyx.

STAM. *Filaments* ten, filiform, smooth, pressed to the germ, the length of the calyx. *Anthers* erect, lanceolate, grooved, terminating in a short point.

PIST. *Germ* superior, longer than the flower, hanging down from it, sabre-shaped, compressed. *Style* ascending, short, filiform. *Stigma* blunt, simple.

PER. *Legume* sword-shaped, narrowed at the base, widening towards the top, ancipital, not opening.

SEED single, round, compressed, in the top of the legume.

ESSENTIAL CHARACTER.

Cal. bell-shaped. *Pet.* five, the uppermost larger. *Germ* longer than the corolla. *Legume* one-seeded.

SPECIES.

Hoitziloxid. *Hern. mex.* 51. *ic.*
Gabureida. *Pis. bras.* 57. 119.

DESCRIPTION, *&c.*

This is a very beautiful tree, with a smooth thick bark, which is very resinous, as all parts of the tree are. Leaves alternate abruptly pinnate. Leaflets in two pairs, mostly opposite, ovate-lanceolate, with the end produced, blunt, emarginate; they are entire, veined and very smooth: rachis running along the whole length of the lower surface of the leaf, rather pubescent: common petiole round, pubescent. Racemes axillary, erect, pointing one way, longer than the leaves; peduncle roundish, pubescent; flowers scattered. Bracte supporting each peduncle, very small, ovate, erect, concave, appearing to the naked eye to be a tubercle. Pedicels erect. Calyx hoary green, on the outside of the orifice surrounded by the petals and anthers which are white, within containing the green legume, and having a singular appearance. The substance of the leaves is full of linear dots, which are transparent and resinous.

The Balsam of Peru is the produce of this tree. The elder Linnæus could never obtain a satisfactory answer to the enquiries which he made concerning the tree that yielded this balsam; at length it was discovered by Joseph Cælestine Mutis in the honest provinces of South America, and he sent a branch of it in flower to the younger Linnæus about the year 1781[a].

According to Jacquin, it is an inelegant shrub, not much branched, erect, eight or ten feet in height. Leaves pinnate, alternate, eight inches long, deciduous, on the younger branches. Leaflets commonly three pairs with an odd one, oblong, blunt, quite entire, smooth, alternate, an inch long, on a short petiole. Racemes loose, terminating, erect, simple or bifid; pedicels one-flowered, erect. Corolla whitish rose-colour, without any scent. Membrane of the fruit veined, large, brownish gray. Seed commonly one, seldom two arriving at maturity, a few more are abortive; the seeds and the cell yield a balsam that has a strong unpleasant smell, whence Jacquin gave this tree or shrub the name of *Myrospermum* or Balsam-seed. He found it growing abundantly in open coppices at the foot of the mountain de la Popa near Carthagena.

MYRRHA. See *Cicuta*.]

MYRRHIS. See *Athamanta, Chærophyllum, Scandix, Sium*.

[MYRSINE. (*Myrsinum of Pliny. Myrsine of Dioscorides.*)

Class. 5. 1. Pentandria Monogynia.
Nat. order of *Bicornes. Sepiariæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, small: *leaflets* suborate, permanent.

COR. one-petalled, half-five-cleft: *segments* half-ovate, converging, blunt.

STAM. *Filaments* five, scarcely visible, inserted into the middle of the corolla. *Anthers* awl-shaped, erect, shorter than the corolla.

PIST. *Germ* subglobular, almost filling the corolla. *Style* cylindric, longer than the corolla, permanent. *Stigma* large, woolly, hanging on the outside of the flower.

PER. *Berry* roundish, depressed, one-celled.

SEED one, subglobular, fixed obliquely to the bottom of the berry. *G.*

OBS. *Unity is frequently subtracted in all parts of the fructification.*
The unripe berry has few seeds, but when ripe it has only one.

ESSENTIAL CHARACTER.

Cor. half-five-cleft, converging. *Germ* filling the corolla. *Berry* one-seeded, with a five-celled nucleus.

2. Myrſine retuſa. *Round-leaved Myrſine* or *Tamoja.*
Ait. hort. kew. 1. 271.
M. ſcabra. *Gærtn. fruct.* 1. 282.
Leaves obovate retuſe emarginate-toothletted at top.

DESCRIPTION, *&c.*

1. Flowers axillary, in threes, on ſhort peduncles. Corolla pale, rugged with teſtaceous dots; ciliate, cloſed. Stamens oppoſite to, not alternate with, the ſegments of the corolla. Stigma pencil-ſhaped. Berry of the ſame form and ſhape with that of Uva urſi, blue. Nucleus of the ſame ſhape, globular, depreſſed a little [a]. Gærtner deſcribes the berry as globular, depreſſed, pulpy, very dark blue with a bloom on it, ſmooth, one-celled. Rind before it is fully ripe ſubcoriaceous, eaſily ſeparating from the inner fleſhy ſpongy ſubſtance, but afterwards very thin and cohering with the pulp. Seeds regularly five, placed round the receptacle in a ring, but only one or at moſt two ripening; that is globular, depreſſed, or hemiſpherical, hollowed near the umbilicus, the reſt ſmooth, ruſeſcent, and very minutely dotted [b].

Native of the Cape of Good Hope. Cultivated in 1691, in the Royal garden at Hampton-court. It flowers from march to may.

2. Native of the Azores, where it was found by Mr. Francis Maſſon. It was introduced in 1788, and flowers in june [c].

Berries the ſize of red Currants, ſpherical, rugged all over with ſmall tubercles. Rind ſubcoriaceous, not coloured, pale or inclined to ſtraw-colour; in other reſpects like the preceding, only every thing ſmaller [d].

α. Long-leaved Pimento.
Leaves oblong-lanceolate acuminate, point blunt.
β. Short-leaved Pimento.
Leaves oval blunt.
Flowers trichotomous-panicled, leaves oblong-lanceolate.

DESCRIPTIONS, *&c.*

[The genus Myrtus is composed of small trees and shrubs. Flowers in some solitary, with two scales at the base and axillary, in others forming opposite corymbs or panicles, axillary or terminating; some are four-petalled with a four-cleft calyx, others have the calyx undivided. The leaves in a very few are sometimes alternate. Perhaps the genus might better be divided from the number of cells in the berry and the situation of the flowers*. Accordingly M. Chytraculia and Syzygium having a one-celled berry are dismissed from this genus, and will be found under that of Calyptranthes.

Dr. Smith observes, that few genera are more confused in the works of Linnæus than this of Myrtus. All that properly belong to it are those that have a corolla of five petals with a five-cleft calyx, and a two-celled or three-celled berry. These characters distinguish it from Eugenia, Psidium and Calyptranthes.

* jelkeu.

The 11th, 18th, 19th, 25th, 29th, 30th, and 36th species have a four-cleft calyx, and four petals to the corolla, but these numbers are by no means constant.

1. The common Myrtle is well known as an elegant evergreen shrub, native of Asia, Africa, and the southern parts of Europe; unfortunately but too tender to abide our winters without some protection in England, except in the most southern and western parts of the island. Trunk irregular, branching, covered with a brown rough scaling bark. Leaves ovate or ovate-lanceolate, entire, smooth on both sides, dark-green paler underneath, opposite and decussated. The flowers come out singly from the axils, and have a two-leaved involucre under them. Corolla white. Berry inferior or below the calyx, subovate, crowned with the permanent calyx, fleshy and spongy, dark purple or black-blue, three-celled. Seeds in each cell four or five, seldom more, kidney-form gibbous, whitish, shining, somewhat bony at the back, the belly filled with a fungous substance, fixed to the inner angle of the cells: they have a single, cartilaginous or somewhat bony, thick cover, no albumen, the embryo conformable to the cavity of the seed, roundish, curved, milk-white: cotyledons semicylindric, short, incumbent: radicle twice the length of the cotyledons, semicircular-curved, inferior[a]. They flower in july and august. The cultivation of the Myrtle in England, is assigned in the Kew catalogue to the year 1629, when Parkinson informs us that he had three sorts (varieties) in his garden; the broad-leaved and two varieties of the box-leaved: Gerarde however, in 1597, says that Myrtles never bear any fruit in England, which surely implies the cultivation of it among us before that period. And Bradley informs us, that the Myrtle was introduced by Sir Francis Carew and Sir Walter Raleigh in 1585, when they resided in Spain, and discovered the preparations for the Spanish Armada against us[b]. Mr. Evelyn also, in the year 1678, says, "I know of one "(a Myrtil) near eighty years old, which has been "continually exposed, unless it be, that in some ex-"ceeding sharp seasons a little dry straw has been "thrown upon it[c]." Perhaps he may allude to the tree at Bedington. But that was the Spanish broad-leaved or Orange-leaved variety, which Miller and Bradley report to have been above eighteen feet high, and to have spread about forty-five feet[d].

Box-leaved and Orange-leaved are said by Johnson (*Ger. emac.* 1233.) to have been nourished in the garden of Mistress Tuggie in Westminster, in 1633.

This shrub was a great favourite among the ancients, for its elegance, and its evergreen sweet leaves. It was sacred to Venus, either on this account, or perhaps because it flourishes most in the neighbourhood of the sea. Myrtle-wreaths adorned the brows of bloodless victors, and were the symbol of authority for magistrates at Athens. Both branches and berries were put into wine, and the latter were used in the cookery of the ancients. The Myrtle was also one of their medicinal plants. All parts of it are astringent, but it is discarded from modern practice.

The principal varieties are erected into species by Mr. Miller. Their differences, as he has given them, are these.]

a. The common broad-leaved or Roman Myrtle grows to the height of eight or ten feet in England, but is much higher in Italy, where it is the principal underwood of some of the forests. The leaves are broader than most of the other varieties, being an inch in breadth; they are an inch and half long, of a lucid green, end in acute points, and are subsessile or on very short foot-stalks. The flowers are larger than those of the other varieties, on pretty long slender peduncles, from two to four at the same axil. Berries ovate or oblong-ovate, very dark purple so that they seem to be black when ripe, including from three to six hard kidney-shaped seeds. This variety is called by some the Flowering Myrtle, because it flowers more freely in England than the others. By others the Roman Myrtle, because it abounds about Rome, where however I did not observe any great quantity of it. The woods between Leghorn and Pisa have Cork-trees for the timber, and Myrtle for the underwood.

β. The Box-leaved Myrtle has the leaves oval, small, sessile, of a lucid green, and ending in obtuse points; the branches weak, and frequently hanging down, when permitted to grow without trimming; the bark is grayish; the flowers are small, and come late in the summer; the berries are small and round.

γ. The common Italian Myrtle has ovate-lanceolate leaves, ending in acute points; the branches grow more erect than in either of the preceding, as do also the leaves, whence it is called by the gardeners Upright Myrtle. The flowers are not large, and the petals are marked with purple at their points, whilst they remain closed. The berries are small, oval and of a purple colour.

There is a variety of this with white berries: and the Nutmeg Myrtle seems to be only a variety of this, several plants raised from the seed of it being so like the Italian Myrtle, as hardly to be distinguished from it.

δ. Orange-leaved, or as it is called by some, bay-leaved Myrtle, has a stronger stalk and branches, and rises to a greater height. The leaves are ovate-lanceolate, in clusters round the branches, and of a dark green. The flowers are of a middling size, and come out sparingly from between the leaves. The berries are oval, and smaller than those of the first. It is not so hardy as that.

ε. The leaves of the Portugal Myrtle are much smaller than those of the next, being less than an inch long, and not more than half an inch broad, lanceolate-ovate acute, of a dull green, and set pretty close on the branches. The flowers are smaller. The berries small and oval.

ζ. The broad-leaved Dutch Myrtle has leaves much less than those of the common sort, and more pointed, standing close together on the branches; the midrib on the under side of the leaves is of a purple colour; they are of a darker green and sit closer to the branches. The flowers are smaller and on shorter peduncles. They come out a little later than the common sort.

The Double-flowering Myrtle is probably a variety of this; the leaves and growth of the plant, the size of the flowers, and the time of flowering agreeing better with this than any of the others.—Mr. Miller, in his plate, has figured the Double Myrtle as a variety of the Italian.

η. Rosemary-leaved, or as some call it Thyme-leaved Myrtle, has the branches growing pretty erect; the leaves small, narrow, acute, sessile, and of a lucid green. Flowers small, appearing late in the season.

The above varieties are constant; others there are which are propagated in the gardens and nurseries for sale, which are less considerable and more variable.

[It may suffice to give the names of these:

1. Gold-striped broad-leaved Myrtle.
2. Broad-leaved Jews Myrtle, having frequently the leaves in threes, on which account it is said to be in esteem among the Jews in their religious ceremonies.
3. Gold-striped Orange-leaved Myrtle.
4. Silver-striped Italian Myrtle.
5. Striped Box-leaved Myrtle.
6. Silver-striped Rosemary-leaved Myrtle.
7. Silver-striped Nutmeg Myrtle.
8. Cock's-comb or Bird's-nest Myrtle.

The Myrtle is a rare instance of the same name prevailing in the Greek and Latin and all the modern European languages, with a very slight difference. Thus in German it is *Myrte* or *Myrtenbaum*; in Dutch, *Myrtus*; in Danish, *Myrter*; in Swedish, *Myrten*; in French, *le Mirte*; in Italian and Spanish, *Mirto*; in Portugueze, *Murta* or *Myrta*.

2. Branches round, tomentose. Leaves an inch and half long, elliptic, blunt, above dark and veined, reflex at the edge, the nerves more conspicuous underneath, smooth above, hoary underneath, on very short petioles. Peduncles axillary and terminating, solitary, opposite, tomentose. Bractes two, small, oblong, at the base of the calyx, which is turbinate and tomentose, with

[a] Gaertner.
[b] Hulls. and Gard. vol. 3. part 2. p. 61.
[c] Sylva, b. 2. ch. 5. p. 174. fol. 1706.
[d] Mill. dict. ed. 1724. Bradl. p. 61.

with four rounded segments. Petals oblong, tomentose-hairy without, purple within [1].

Loureiro thus describes it under the name of M. cauliflora; ſtems ſhrubby, erect, ſix feet high, manifold, ſmooth, whitiſh, even; with ſpreading branches. Leaves ovate, ſometimes acute, quite entire, three-nerved, hoary; on petioles connate with the ſtalk. Flowers purpliſh, ſolitary, ſcattered, having a large, berried, five-cleft calyx, with rounded, ſpreading, unequal ſegments, and an involucre of two ſmaller leaves underneath. Petals five, roundiſh, ſpreading, longer than the calyx. Stamens nearly equal to the corolla. Berry ovate, crowned, tomentoſe, black-purple, three-celled, with a juicy, blackiſh, ſweet-auſtringent, eſculent pulp, and many, minute, roundiſh ſeeds.

Native of China and Cochinchina. Introduced about 1776, by Mrs. Norman. It flowers in June and July [2].

3. Native of Jamaica.

4, 5, 6. Natives of Hiſpaniola [3].

7. The whole of this ſhrub is ſmooth. Branches round, with an aſh-coloured bark. The young twigs have linear-lanceolate ſcales, at firſt imbricate, but afterwards remote and deciduous. Leaves petioled, an inch long, blunt, the upper ſurface ſomewhat veined and ſhining, with a groove along the middle, the under veinleſs, pale, dotted in cluſters. Peduncles ſometimes four from the ſame bud, uſually axillary oppoſite and terminating, but often below the leaves, one-flowered, filiform, an inch and half long. Segments of the calyx oblong, blunt. Petals oblong, blunt, ſmall, white.—Native of the Caribbee iſlands [4].

The fruit has a very thin black ſkin, with a very ſmall purple ſweetiſh pulp, including two white ſtones, flat on one ſide, convex on the other, together making a ſphere. It is ſo like a black Cherry, that it has that name in Jamaica [5].

8. This is an elegant little ſhrub, with leaves ſomewhat more than an inch in length, and about a line in breadth, ſlightly revolute, downy beneath. Flower-ſtalks ſilky, ſhorter than the leaves, each bearing a ſmall white flower, often tinged externally with red, and not unlike the common Myrtle bloſſom, though ſcarcely half ſo large. Calyx nearly ſmooth. Petals downy. Germ very ſilky.—Native of New South Wales [6].

9. Leaves ovate, obtuſe, petioled, ſmooth. Flowers axillary, on a leafleſs peduncle. Petals four or five, lacerate-ciliate, obovate, concave, reflex. Stamens about forty.—Native of Braſil [7].

This plant ſtands in the latter editions of Linnæus in three different places, being his *Eugenia uniflora*, *Myrtus braſiliana* and *Plinia peduncularis* [8]. See *Eugenia* and *Plinia*.]

10. This riſes with a divided trunk to the height of eight or ten feet, ſending out many oppoſite branches, covered with a gray bark. Leaves ſhorter and rounder at the points, ſmoother and of a firmer texture than in M. Pimenta. The flowers come out from the ſide of the branches between the leaves, on ſlender foot-ſtalks, about an inch in length, two generally from the ſame point. Berries round, of a brighter colour than the Pimenta. The leaves and fruit not having the aromatic flavour of Pimenta are not in uſe.

This tree retaining its leaves, which are of a ſplendent green, all the year, it makes a good appearance; but the flowers being ſmall, and growing thinly upon the branches, do not make any great figure. It is a native of Jamaica, whence Mr. Miller received it, and cultivated it ſome years before 1759.

[Browne ſays, it is a beautiful little ſhrub, riſing commonly to the height of three or four feet, ſometimes more.

11. Leaves large and handſome. Flowers ſmall, generally three together, on ſhort hairy forked flower-ſtalks. Although the teeth of the calyx, and the petals alſo, are generally four only, it is a true Myrtus, and not an Eugenia, the fruit being a berry with many ſhining gibbous curved ſeeds. It has but one cell when ripe, but the germ appears to be divided into two or three cells.—Native of New South Wales [9].

Loureiro has a different ſpecies under the ſame name. He deſcribes it as a tree twelve feet in height, with ſpreading branches. Leaves ovate, acuminate, quite entire, three-nerved, ſmooth on both ſides, petioled. Flowers white, ſubterminating, in long racemes. Calyx berried, four-cleft. Corolla four-petalled. Berry roundiſh, crowned, brown, ſmooth, one-celled, with a few, unequal, angular ſeeds. The berries are ſcarcely half an inch in diameter, and are eatable.—Native of Cochinchina.

12. This reſembles M. biflora. It is a ſmall tree with round branches and ſquare ſmooth twigs. Leaves like thoſe of Phillyrea angustifolia, ſubſeſſile, long, linear-lanceolate, quite entire, ſmooth, ſeveral times longer than the internode. Peduncles lateral, oppoſite, ſhort, ſcarcely longer than the internode, having an umbellet at top uſually ſimple, ſeldom compound, ſmall, many-flowered. Petals roundiſh. Stamens erect, briſtle-ſhaped, longer than the petals.—Native of the Cape of Good Hope [10].

13. Stem ſhrubby, entirely ſmooth. Branches and branchlets alternate, erect. Leaves from the alternate buds, ſingle in pairs or in threes, ſharply ſerrate, veined, ſmooth on both ſides, pale underneath, ſpreading, unequal, an inch long and more, on petioles half a line in length. Flowers on the branchlets terminating, in a ſimple umbel. Peduncles filiform, warted with ſcars, an inch long. Perianth five-toothed, ſmooth. Berry two-celled or three-celled, with one ſeed in each cell. It is nearly allied to *Crataegus villoſa* and *Levis*. From the firſt however it differs in being wholly ſmooth, in having one piſtil, and aggregate leaves: from the ſecond, in having one piſtil, and ovate ſlender leaves, longly acuminate.—Native of Japan [11].

14. The leaves are of a ſingular ſtructure, being from ovate remarkably attenuated into a lanceolate top. Flowers five-petalled.—Native of Surinam [12].

15. This is a tree with round, aſh-coloured branches. Leaves lanceolate or ovate-lanceolate, ſmooth, quite entire, not very acute, on longiſh petioles. Corymbs trifid, compound, lateral [13].—Native of the Eaſt Indies.

16. Native of Hiſpaniola [14].

17. Branches aſh-coloured, ſmooth, as is the whole plant, compreſſed at top. Leaves an inch long, ſomewhat leathery, margined, very blunt and ſmooth, veined, dotted underneath and paler. Flowers axillary and on the leafleſs branches, ſeſſile, three or four on each ſide [15].—Native of the Weſt Indies.

18. Branches round, aſh-coloured, compreſſed a little at top. Leaves two inches long, blunt, ſomewhat coriaceous, very ſmooth and even, veinleſs, having a groove along the middle, and a nerve within the edge as in M. zeylanica. Petioles very ſhort, purpliſh. Peduncles in pairs, ſcarcely half an inch long, villoſe aſh-coloured. Pedicels the ſame colour, and a little longer than the peduncle; decuſſated, commonly one-flowered. One ovate minute bracte at the baſe of each pedicel, and two others very like it at the baſe of the calyx; which is villoſe aſh-coloured and coriaceous, with four oblong ſegments. Petals twice as long as the calyx, very minutely ciliated. Stamens the length of the petals.

19. Branches with a coated chinky bark. Leaves two inches long, membranaceous, with numerous, ſimple, tranſverſe veins, having a longitudinal nerve within the edge on each ſide, paler underneath, on ſhort petioles; the young ones are villoſe-ſilky. Racemes ſolitary or in pairs oppoſite, ſcarcely a quarter of an inch in length, four-flowered. Pedicels one-flowered, oppoſite. A minute bracte at the baſe of each pedicel, and two minute ones at the baſe of the calyx; which is oblong, ſubvilloſe, with oblong ſegments, almoſt the length of the germ. Petals four.—It differs from M. glabrata of Swartz in having flat membranaceous leaves, and few-flowered racemes: from M. diſticha of the ſame author, by its few-flowered pedicels, and leaves not

[1] Vahl. [2] Hort. kew. [3] Swartz. [4] Vahl. [5] Sloane. [6] Smith in Linn. trans. [7] Linn. ſpec. [8] Smith in Linn. trans. [9] Idem. [10] Linn. amæn. [11] Thunberg. [12] Linn. ſpec. [13] Linn. ſuppl. [14] Swartz. [15] Vahl.

not bent down. This and the preceding are natives of South America, and were communicated to Vahl by Mr. Forsyth [a].

20. Native of the West Indies.

21. Native of Hispaniola.

22, 23, 24. Natives of Jamaica.

25. Calyx four-parted, with rounded, concave segments. Corolla four-petalled. Germ two-celled. Berry one-celled, obovate-globular, rugged with dots, coriaceous, pale straw-colour. Seed one, large, kidney-oblong, fleshy. Cotyledons so entangled together that they can scarcely be separated"—Native of Antigua, Barbados, Dominica. Introduced in 1776 by John Greg, Esq.[b]

26. Leaves thick. Pedunicles axillary and terminating, brachiate-panicled, the length of the leaves. Petals few.—Native of America. Communicated to Linnæus by Miller [c].

27. Branches rod-like, smooth, with an ash-coloured bark, the young ones villose. Leaves petioled, an inch and half or more in length, sharpish at the base, smooth above and shining, pale underneath and veined; the younger ones somewhat downy above. Peduncles paniculate, in pairs from each axil, shorter by half than the leaves. Pedicels opposite, remote, a quarter of an inch long, filiform, one-flowered. Bractæ ovate, minute, at the base of each pedicel, and two under each calyx. Flowers small. Segments of the calyx rounded, ash-coloured at the base. Petals twice as long as the calyx, downy [d].—Native of Jamaica, Santa Cruz, &c.

28. Native of Hispaniola [e].

29. This has a strong upright stalk, covered with a smooth gray bark, dividing towards the top into many slender stiff branches. Leaves near two inches long, and an inch and quarter broad, of a lucid green, and on very short foot-stalks. The flowers come out at the ends of the branches, several on one common peduncle, which branches out; and each flower stands on a very slender pedicel: they are very like the flowers of the Italian Myrtle.

[Branches round, ash-coloured: branchlets compressed, purplish, subalternate. Leaves on very short petioles; sometimes subalternate, an inch and half long, subcoriaceous, blunt, veinless, very smooth, having a longitudinal groove in the middle. Peduncles opposite, four-cornered, two inches long, smooth, having raised wandering dots: pedicels opposite, four-cornered, remote, scarcely half an inch long; flowers commonly four from the top of each pedicel, on other short pedicels. Calyx turbinate, wrinkled with raised gray scattered tubercles, having four rounded segments [f]. In Linnæus's Flora Zeylanica, the calyxes are said to be five-toothed, the corollas five-petalled, and the berries white. According to Lourciro, the calyx is four-cleft, the corolla four-petalled; the stamens about one hundred in number; the berry white, small, roundish, one-celled, containing about eight seeds: but he doubts whether his plant be the same with Herman's.

Native of Ceylon; probably of other parts of the East Indies and of Cochinchina. Cultivated by Mr. Miller before 1759.

30. The whole plant is smooth. Branches obscurely four-cornered at top. Leaves very large, being a hand or more in length, veined, a little attenuated at top, blunt, not dotted on either side. Terminating racemes two, sometimes four together, the axillary ones opposite, solitary; all brachiate, three inches long. Peduncles four-cornered; partial ones opposite, spreading very much, remote; the lower ones trifid, with three-flowered pedicels. Bractæ awl-shaped, very short at the base of each peduncle and pedicel, none at the base of the calyx; which is obovate, the size of a pepper-corn and four-toothed [g].

Lourciro describes the species to which he gives this name, as a very branching small tree or shrub, five feet high, with reddish-white flowers, the calyx five-toothed, the corolla five-petalled. Berry dusky-red.

Native of Ceylon, and perhaps of Cochinchina.

31. This is a tree with round branches. Leaves smooth, quite entire, blunt, subpetioled. Corymbs terminating the branches, compound, divided three ways. Calyxes undivided, quite entire [h]. Berries two-celled, two-seeded [i].

Native of Ceylon and other parts of the East Indies; not of America.

32. This may contend the palm of elegance with most trees. It grows slowly, and flowers late, twice in a year. By age it acquires thickness and height beyond mediocrity. Trunk handsome, straight, forming a very lofty thick beautiful pyramidal head. Bark in the younger trees brown, then ash-coloured, finally white entirely, or with large yellow spots; it is very smooth and even, especially in old trees, but here and there hangs down in slender shreds; the flavour is astringent, not without something of aromatic. Timber very hard, red, compact, ponderous, and capable of being polished; used for the cogs of wheels in the sugar mills, and other works where considerable friction is required. The younger branches are acutely four-cornered and green. Leaves numerous, quite entire, shining, bright green, with transverse veins, blunt, attenuated into a short petiole; they are always opposite, commonly three or four inches long, of a very sweet aromatic smell, and on account of their agreeable astringency are used for sauce with food. Flowers small, white with a slight tinge of redness. Berries round, the size of peas, crowned with the remains of the calyx, having an aromatic smell and taste, which render them agreeable for culinary purposes; they contain about seven or eight seeds.

Native of the West Indies; Martinico, Guadaloupe and Grenada, where it is called *Bois d'Inde*, and is supposed to have been introduced from the East Indies [k]. It is however a different species from the M. caryophyllata of that country.

Browne says it is common in Antigua and Jamaica, as well as Barbadoes, and grows generally to a considerable size, that it fills the woods with the fragrant smell of its leaves, nearly resembling that of Cinnamon, but that the bark has no warmth of that sort, though the berries resemble Cloves very much, both in form and flavour. It is commonly called Wild Cinnamon or Wild Clove tree in Antigua and Jamaica. It is the Bayberry of Hughes, plate 10.

33. The whole of this plant is smooth. Leaves petioled, an inch long, emarginate, from a reflex margin becoming convex, the upper surface shining very much, veinless, transversely but obliquely marked with dusky nerved lines; the under surface less shining; the younger leaves veined on both sides, with minute raised dots scattered over the under surface, which vanish in the older leaves, and they have dusky spots impressed on the upper surface. Peduncles purplish, twice as long as the leaves, subracemose, in pairs. Pedicels opposite, commonly four, very remote, three-flowered. Flowers pedicelled. Calyx purplish, with roundish segments. Petals oblong, small. Fruit globular, the size of a pepper-corn [l].

Native of the West Indies.] Sent to Mr. Philip Miller by Mr. Robert Millar, surgeon, from Carthagena in New Spain.

[34. Branches subdichotomous, smooth, purplish at the end. Leaves subpetioled at the ends of the branchlets, an inch and half long, bluntish, with numerous simple veins not reaching the edge on either side, and minute raised dots scattered over them. Peduncles from the top, two, three-flowered, the length of the leaves, compressed: pedicels three-flowered: flowers sessile [m].—Native of Jamaica and Guiana.

35. This is an upright shrub, a foot and half high, with few, ascending branches. Leaves alternate, subsessile, with short very acute serratures. Flowers white, subterminating. Calyx five-cleft, with the segments acute, spreading. Corolla five-parted, with the parts ovate, concave, united at the base into a very short tube. Filaments about thirty, equal to the corolla. Anthers roundish. Germ roundish. Style fili-

[a] Vahl symb. [b] Gaertner. [c] Hort. Kew. [d] Linn. spec. [e] Vahl. [f] Swartz. [g] Vahl. [h] Idem. [i] Linn. syst. [k] Juss. gen. [l] Jacquin. [m] Vahl. [n] Idem.

form, equal to the ſtamens. Stigma thickiſh. Berry roundiſh, crowned, two-celled; with a few ovate ſeeds. Native of China near Canton[1].]

36. This tree grows to the height of thirty feet or more, with a ſtraight trunk, covered with a ſmooth brown bark, dividing upwards into many branches which come out oppoſite, garniſhed with oblong leaves, reſembling thoſe of the Bay-tree in form, colour, and texture, but longer, and placed by pairs: when theſe are bruiſed or broken, they have a very fine aromatic odour like that of the fruit. The branches grow very regular, ſo that the trees make a fine appearance, and as they retain their leaves through the year, the trees are worthy of being propagated for ornament and ſhade about the habitations of the planters. The flowers are produced in large looſe bunches from the ſide of the branches, towards their ends, each branch is alſo terminated by a larger bunch than the other; the flowers are ſmall, and of an herbaceous colour.

[Mr. Miller ſays they are male and female upon diſtinct trees, and deſcribes both. Swartz informs us that the Pimento is a polygamous tree, having the barren and fertile flowers either together, or on a diſtinct tree; that the calyx, which is called the fruit, or is inferior, is preſent in moſt of the ſpecies, but by no means ſuffices for the character of a diſtinct genus, rather performing the office of a bracte; and that the berry is moſt commonly one-ſeeded, though ſometimes it ſeems to be three-ſeeded.

Browne ſays, that ſome of theſe trees are frequently obſerved to be barren, which has introduced a notion among the people of Jamaica, of their being male and female trees in general, and that ſome of the male or barren trees were requiſite in every walk; all thoſe however that he obſerved bore only hermaphrodite flowers, and he was credibly informed that thoſe called male trees, when lopped and broken like the reſt for one or two years, bear very well; which he is the more apt to believe, as he never obſerved a diſtinct male or female flower on any of them.

He deſcribes the root as branched and ſpreading, the trunk ſmooth and ſhort, ſeldom above eight or ten inches in diameter, the top generally pretty much divided, and riſing in cloſe tufts, the leaves and bark very warm, and full of aromatic particles, which makes the planters very cautious of fire in all Pimento walks, where, if it ſhould once catch, it would run with great fury.

Linnæus ſays, that the calyx of the fruit is inferior and four-toothed, but the calyx of the flower ſuperior and four-parted; and that the berry has two ſeeds.

Gærtner deſcribes the berry as ſpherical, crowned with the calyx, which is flattiſh, depreſſed and five-notched; it is fleſhy, two-celled, and gratefully aromatic: receptacle in the upper part of the partition. Seeds two, rounded-kidney-form, ſomewhat convex on one ſide, flat on the other, rufeſcent, not ſhining. Integument ſingle, ſomewhat membranaceous, thin. No albumen. Embryo roundiſh. Cotyledons linear-acuminate, very ſhort. Radicle very long, thick, ſpirally convoluted, aſcending or ſuperior.

The Pimento tree is a native of the Weſt Indies, and flowers in June, July and Auguſt. The berries are chiefly imported into England from Jamaica, whence the name Jamaica Pepper. It is alſo named All-ſpice, from a notion of its taſte being compounded of ſeveral other ſpices.—Mr. Miller cultivated it in 1739[2].

This tree begins to bear fruit in three years after it is planted, but does not arrive at maturity under ſeven; it then repays very abundantly the patience of the planter, yielding one thouſand pounds weight of fruit from an acre. They are generally gathered in July, in their green ſtate, by twiſting off the twigs with the hand, or a pole cleft at one end; and are laid on cloths ſpread over the barbacues or terraced floors raiſed a little above the ground, incloſed with an upright ledge of eight or ten inches in height, and divided by trankverſe partitions into four or more ſquare compartments, that each may contain a day's picking. During the firſt and ſecond day they are turned often, that the whole may be more expoſed to the ſun; but when they begin to dry, they are frequently winnowed, and laid in cloths to preſerve them better from rain and dews, ſtill expoſing them to the ſun every day, and removing them under cover every evening, till they are ſufficiently dried, which uſually happens in ten or twelve days, and is known by the darkneſs of their complexion, and the rattling of the ſeeds, they appear at this time wrinkled and changed to a very dark brown. In this ſtate, being ready for the market, they are ſtowed in bags or caſks. Some planters kiln dry them with great ſucceſs. Such of the berries as come to full maturity, like many other ſeeds, loſe that aromatic warmth for which they are eſteemed, and acquire a taſte perfectly like that of Juniper berries; which renders them a very agreeable food for the birds, the moſt induſtrious planters of theſe trees.

The berries have an agreeable aromatic ſubaſtringent taſte, which recommends them both in the kitchen, and the druggiſt's ſhop. A delicate aromatic oil is diſtilled from them, which anſwers all the purpoſes for which the oils of Cinnamon and Cloves have been generally uſed, and is thought by ſome to be better than either, as it joins an aſtringency with its warmth. All parts of the tree are more or leſs aromatic and ſubaſtringent, but the leaves ſeem to abound moſt in volatile warm particles[3].]

Mr. Miller was informed by an eminent merchant, through whoſe hands great quantities of the commodity paſſed, that the Dutch purchaſed All-ſpice of the Engliſh at a low price, and grinding it, ſold it again to us at an advanced price for powder of Cloves: and that they draw an oil from it, which they vend for oil of Cloves. Mr. Miller had a phial of this oil ſent him from Jamaica, which was ſhown to ſome of the beſt judges of drugs in London, who having tried it, declared they thought it as good as any oil of Cloves they had ſeen. He ſuggeſts, as worthy of trial, to dry the fruit when firſt formed, as a ſuccedaneum for oriental Cloves.

[All-ſpice, which was at firſt brought over for dietetic purpoſes, has been long employed in the ſhops as a ſuccedaneum to the more coſtly oriental aromatics. It is moderately warm, of an agreeable flavour, ſomewhat reſembling that of a mixture of Cloves, Cinnamon and Nutmeg. Diſtilled with water it yields an elegant eſſential oil, ſo ponderous as to ſink in the water, in taſte moderately pungent, in ſmell and flavour approaching to oil of Cloves, or rather a mixture of Cloves and Nutmegs. To rectified ſpirit it imparts by maceration or digeſtion, the whole of its virtue: in diſtillation it gives over very little to this menſtruum, nearly all its active power remaining concentrated in the inſpiſſated extract.

Pimento can ſcarcely be conſidered as a medicine: being however an agreeable aromatic, it is not unfrequently employed with different drugs, requiring ſuch a grateful adjunct. In the London Pharmacopœia both an aqueous and ſpirituous diſtilled water of the berries is directed, and the powder of them is an ingredient in Syrup of Buckthorn. The Edinburgh College order alſo the Eſſential Oil[4].]

PROPAGATION AND CULTURE.

1. All the varieties of the Common Myrtle may be propagated from cuttings, the beſt ſeaſon for which is the beginning of July, when you ſhould make choice of ſome of the ſtraighteſt and moſt vigorous young ſhoots, which ſhould be about ſix or eight inches long, and the leaves on the lower part muſt be ſtripped off about two or three inches high, and the part twitted which is to be placed in the ground; then having filled a parcel of pots (in proportion to the quantity of cuttings deſigned) with light rich earth, you ſhould plant the cuttings therein, at about two inches diſtance from each other, obſerving to cloſe the earth faſt about them, and give them ſome water to ſettle it to the cuttings; then place the pots under a common hot-bed frame, plunging them either into ſome old dung, or tanners-barks, which will prevent the earth from drying too faſt; but you muſt carefully ſhade them

[1] Loureiro [2] Hort. kew. [3] Browne, 248, and Long, vol. 3. p. 702. [4] Woodville.

with

with mats in the heat of the day, and give them air in proportion to the warmth of the ſeaſon, not forgetting to water them every two or three days, as you ſhall find the earth in the pots require it.

With this management, in about ſix weeks, the cuttings will be rooted, and begin to ſhoot, when you muſt inure them to the open air by degrees, into which they ſhould be removed towards the latter end of auguſt, or the beginning of ſeptember, placing them in a ſituation where there may be ſheltered from cold winds, in which place they may remain till the middle or latter end of october, when the pots ſhould be removed into the green houſe, but ſhould be placed in the coolеſt part thereof, that they may have air given to them whenever the weather is mild, for they require only to be protected from ſevere cold, except the Orange-leaved, and the ſtriped Nutmeg Myrtles, which are ſomewhat tenderer than the reſt, and ſhould have a warmer ſituation.

During the winter ſeaſon, they muſt be frequently, but gently watered; and if any decayed leaves appear, they ſhould be conſtantly picked off, as alſo the pots kept clear from weeds, which, if permitted to grow, will ſoon overſpread the young plants, and deſtroy them.

If theſe pots are placed under a common hot-bed frame in winter, where they may be ſereened from froſt, and have the free air in mild weather, the young plants will ſucceed better than in a green-houſe, provided they do not receive too much wet, and are not kept cloſely covered, which will occaſion their growing mouldy, and dropping their leaves.

The ſpring following theſe plants ſhould be taken out of the pots very carefully, preſerving a ball of earth to the roots of each of them, and every one ſhould be placed into a ſeparate ſmall pot filled with rich light earth, obſerving to water them well to ſettle the earth to their roots, and place them under a frame until they have taken root; after which they ſhould be inured to the open air, and in may they muſt be placed abroad for the ſummer, in a ſheltered ſituation, where they may be defended from ſtrong winds.

During the ſummer ſeaſon they will require to be plentifully watered, eſpecially being in ſuch ſmall pots, which in that ſeaſon ſoon dry; therefore you ſhould obſerve to place them where they ſhould receive the morning ſun, for when they are too much expoſed to the ſun in the heat of the day, the moiſture contained in the earth of theſe ſmall pots will ſoon be exhaled, and the plants greatly retarded in their growth thereby.

In auguſt following you ſhould examine your pots, to ſee if the roots of the plants have not made way out through the hole in the bottom of the pots, which if you obſerve, you muſt then ſhift them into pots a ſize larger, filling them up with the like rich earth, and obſerve to trim the roots which were matted to the ſide of the pots, as alſo to looſen the earth from the outſide of the ball with your hands, ſome of which ſhould be taken off, that the roots may the eaſier find paſſage into the freſh earth; then you muſt water them well, and place the pots in a ſituation where they may be defended from ſtrong winds; and at this time you may trim the plants, in order to reduce them to a regular figure; and if they are inclinable to make crooked ſtems, you ſhould thruſt down a ſlender ſtraight ſtick cloſe by them, to which their ſtems ſhould be faſtened, ſo as to bring them upright.

If care be taken to train them thus while they are young, the ſtems afterwards when they have acquired ſtrength, will continue ſtraight without any ſupport, and their branches may be pruned, ſo as to form either balls or pyramids, which for ſuch plants as are preſerved in the green-houſe, and require to be kept in ſmall compaſs, is the beſt method to have them handſome; but then theſe thereed plants will not produce any flowers, for which reaſon that ſort with double flowers ſhould not be clipped, becauſe the chief beauty of that conſiſts in its flowers; but it will be neceſſary to ſuffer a plant or two of each kind to grow rude, for the uſe of their branches in noſegays, &c. for it will greatly deface thoſe which have been conſtantly ſheered to cut off their branches.

As theſe plants advance in ſtature, they ſhould annually be removed into larger pots, according to the ſize of their roots; but you muſt be careful not to put them into pots too large, which will cauſe them to ſhoot weak, and many times prove the deſtruction of them; therefore when they are taken out of the former pots, the earth about their roots ſhould be pared off, and that within ſide the ball muſt be gently looſened, that the roots may not be too cloſely confined; and then place them into the ſame pots again, provided they are not too ſmall, filling up the ſides and bottom of them with freſh rich earth, and giving them plenty of water to ſettle the earth to their roots; which ſhould be frequently repeated, for they require to be often watered both in winter and ſummer, but in hot weather they muſt have it in plenty.

The beſt ſeaſon for ſhifting theſe plants is either in april or auguſt, for if it be done much ſooner in the ſpring, the plants are then in a ſlow growing ſtate, and ſo not capable to ſtrike out freſh roots again very ſoon; and if it be done later in autumn, the cold weather coming on will prevent their taking root; nor is it adviſeable to do it in the great heat of ſummer, becauſe they will require to be very often watered, and alſo to be placed in the ſhade, otherwiſe they will be liable to droop for a conſiderable time; and that being the ſeaſon when theſe plants ſhould be placed amongſt other exotics, to adorn the ſeveral parts of the garden, theſe plants, being then removed, ſhould not be expoſed until they have taken root again, which, at that time (if the ſeaſon be hot and dry) will be three weeks or a month.

In october, when the nights begin to be froſty, you ſhould remove the plants into the green-houſe; but if the weather proves favourable in autumn (as it often happens) they may remain abroad until the beginning of november; for if they are carried into the green-houſe too ſoon, and the autumn ſhould prove warm, they will make freſh ſhoots at that ſeaſon, which will be weak, and often grow mouldy in winter, if the weather ſhould be ſo ſevere as to require the windows to be kept cloſely ſhut, whereby they will be greatly defaced; for which reaſon they ſhould always be kept as long abroad as the ſeaſon will permit, and removed out again in the ſpring before they ſhoot out; and during the winter ſeaſon that they are in the green-houſe, they ſhould have as much free air as poſſible when the weather is mild.

The Common broad-leaved, broad-leaved Dutch, and Portugal Myrtles may be planted, abroad in warm ſituations, and upon a dry ſoil, where they endure the cold of our winter very well, with only being covered in very hard froſts with mats, and the ſurface of the ground about their roots covered with a little mulch to prevent the froſt from entering the ground; but in Cornwall and Devonſhire, where the winters are more favourable than in moſt other parts of England, there are large hedges of Myrtle which have been planted ſeveral years, and are very thriving and vigorous, ſome of which are upwards of ſix feet high; and I believe, if the double flowering kind were planted abroad, it would endure the cold as well as any of the other ſorts, it being a native of the ſouthern parts of France. This, and the Orange-leaved, are the moſt difficult to take root from cuttings; but if they are planted towards the latter end of june, making choice of only ſuch ſhoots as are tender, and the pots are plunged into an old bed of tanner's bark which has loſt moſt of its heat, and the glaſſes ſhaded every day, they will take root extremely well. The Orange-leaved, and thoſe with variegated leaves, are ſomewhat tenderer than the ordinary ſorts, and ſhould be houſed a little ſooner in autumn, and placed farther from the windows of the green-houſe.

2d. This plant is with difficulty propagated, which occaſions its preſent ſcarcity, for as it does not produce ripe ſeeds in Europe, it can only be increaſed by layers or cuttings. By the former method the layers are commonly two years before they take root, and the cuttings frequently fail, though the latter is preferred,

when performed at a proper ſeaſon and in a right method; the beſt time to plant the cuttings is in may: in the choice of them, it ſhould be the ſhoots of the former year, with a ſmall piece of the two years wood at bottom; theſe ſhould be planted in ſmall pots, filled with ſoft loamy earth, for ſmall pots are to be preferred to large ones for this purpoſe, and they ſhould be plunged into a very moderate hot-bed of tanners bark; and if the pots are each covered with ſmall bell or hand-glaſſes, ſuch as have been uſed for blowing Carnations to exclude the air, it will be of great ſervice to promote the cuttings putting out roots, though they are covered with the glaſſes of the hot-bed above them; the cuttings ſhould be ſhaded from the ſun in the heat of the day, and gently refreſhed with water, as the earth in the pots is found to dry, but they ſhould by no means have too much wet: thoſe cuttings which ſucceed, will have taken root by july, when they ſhould be gradually inured to bear the open air, into which it will be proper to remove them about the middle of that month, that they may be ſtrengthened before winter, but it will not be proper to tranſplant the cuttings till ſpring; the pots muſt be removed into a temperate ſtove in autumn, and during the winter the cuttings muſt be gently refreſhed with water. In the ſpring they ſhould be carefully taken up, and each planted in a ſmall pot filled with light earth from a kitchen-garden, and plunged into a moderate hot-bed to forward their taking freſh root; then they ſhould be gradually hardened, and in july placed in the open air in a ſheltered ſituation, where they may remain till the end of ſeptember, and then be removed into the ſtove.

This plant will not live through the winter in England in a green-houſe, but if it is placed in a moderate degree of warmth, it will flower well in winter; and in july, auguſt and ſeptember the plants ſhould be placed abroad in a ſheltered ſituation.

[The other tender Myrtles from the Eaſt and Weſt Indies may be treated in the ſame manner.]

36. This tree is propagated by ſeeds, which in the natural place of its growth are conveyed, and ſown by birds, to a great diſtance; and, it is very probable, the ſeeds paſſing through them, are rendered fitter for vegetation, than thoſe which are immediately gathered from the tree; for I have received great quantities of the berries which were perfectly ripe and freſh, great part of which I ſowed in different ways, and communicated ſome of them to ſeveral other curious perſons, who did the ſame, but none of them have yet ſucceeded; and upon informing my friend Mr. Williams of this, he told me that a friend of his, whoſe plantation was on the ſouth ſide of Jamaica, deſired him to ſave a large quantity of the ripe berries for him to ſow on his plantation, which he accordingly did, but his friend forgot to ſend for them till near two years after; during which time, they had lain in a large heap, and had fermented, and, on ſowing thoſe berries, the plants came up with the firſt rains in great abundance; ſo that it may be of great ſervice to theſe ſeeds, either to paſs through animal bodies, or to be fermented before they are ſown.

The plants cannot be preſerved in England unleſs they are placed in a ſtove during the winter ſeaſon, but they will thrive in a moderate degree of warmth: they ſhould be planted in a ſoft light ſoil, and in winter muſt have but little water. In the ſummer they ſhould have a large ſhare of air, and in july, if the ſeaſon proves warm, they may be placed in the open air, in a warm ſheltered ſituation; but upon the approach of cold nights, they muſt be removed into the ſtove again. The expoſing of theſe plants to the open air for one month only, will be of great ſervice to clean their leaves from inſects or filth, which they are ſubject to contract, by remaining long in the ſtove: but if the ſeaſon ſhould prove very wet or cold, it will not be ſafe to truſt theſe plants long abroad; therefore their leaves ſhould be now and then waſhed with a ſponge to clean them, which will not only render them more ſightly, but alſo promote their growth.

This tree is pretty difficult to propagate in England, where the ſeeds do not ripen: the only method in which this has been done, is by laying down the young branches, ſlitting them at a joint in the ſame manner as is practiſed in making layers of Carnations. If this is carefully performed, and the layers are regularly but gently watered, they will put out roots in one year; then they may be carefully ſeparated from the old plants, and each planted in a ſmall pot filled with light earth, and plunged into the tan-bed, either in the ſtove or under a frame, being careful to ſhade them until they have taken new root, after which they may be treated as the older plants. This plant, being an Evergreen, makes a fine appearance in the ſtove at all ſeaſons of the year; and the leaves having ſuch an agreeable fragrancy when rubbed, renders them as worthy of a place in the ſtove, as any other tender exotic plant which is preſerved for ornament.

As theſe plants do not riſe ſo readily from ſeeds in England, the beſt way to obtain them is to get ſome perſon of ſkill in America, to take up a number of young plants, and plant them cloſe in boxes of earth, ſetting them in the ſhade till they have taken new root; then remove them into an open ſituation where they may have time to eſtabliſh their roots before they are ſhipped for England; and in their paſſage they muſt be guarded from the ſpray of the ſea, and ſalt water, and ſhould have very little water given them; for moſt of the plants which are ſent to England, are killed in their paſſage by having too much wet. If theſe directions are obſerved, the plants may be brought in good health to England, provided they come over any time in the ſummer, that they may have time to get freſh root before the cold ſeaſon begins; and when once they are well eſtabliſhed in their roots here, they may be preſerved many years in vigour; but I have not ſeen many of the plants in flower here as yet.

DESCRIPTION, *&c.*

Stem wide, having triangular fpines fcattered over it. Leaves firm narrow with very fimilar toothed fpines on each fide. Flowers folitary from the axils of the leaves, male and female near each other: the males drooping on a fhort petiole; the females feſſile erect [a].

According to Juſſieu, it has three whorled fheathing leaves, the flowers axillary feſſile, the filament in the male flowers long, with a four-valved anther, which is the four-cleft corolla of Linnæus; in the female flowers two ſtigmas, and one nut or four feeds.

Native of the ſea coaſt of Europe; in the canal between Piſa and Leghorn; and in the Rhine near Baſle.

DESCRIPTION, *&c.*

Root ſimple, thready. Stem herbaceous, from two inches to half a foot in length, ſubdivided, procumbent, pubeſcent, tender, three-winged from the decurrent petioles. Branchlets from the axils of the leaves procumbent. Leaves oppoſite, wedge-ſhaped at the baſe, ovate-roundiſh, entire, pubeſcent. Petioles decurrent at the ſides, the wings converging to the ſide oppoſite to the petiole. Flowers axillary, two to four, in cluſters, ſmall, white, on ſhort peduncles. Calycine ſegments linear, erect, ſomewhat hirſute. Tube of the corolla narrower at the baſe, a little longer than the calyx: ſegments of the border roundiſh, erect, convex, incumbent not ſpreading. Filaments from the baſe of the corolla, wider at bottom, awl-ſhaped. Anthers roundiſh. Germ oblong, conical. Styles contiguous. Stigmas blunt. Capſule oblong, blunt, four-cornered, acuminate, one-celled, two valved; containing many, minute, roundiſh, brown ſeeds [b].

According to Gærtner, the capſule is roundiſh (teretiuſcula) marked with a groove on each ſide, two-celled, two-valved, the valves when ripe becoming bifid: partition contrary to the valves, formed by their margins bent in. Receptacle compoſed of two membranaceous linear acuminate lamiæ, placed in the axis of the capſule and at the meeting of the partitions, free, and ſupporting the ſeeds in a double row in each cell. Seeds ſubglobular, ſmall, ſcrobiculate or ſtriated lattice-wiſe.

Browne ſays, that this little plant ſpreads about the root, and ſeldom grows above five or ſix inches in length; that the whole of it is ſomewhat hairy, with the ſtalk and branches margined.

It is an annual plant, native of Jamaica, in cultivated grounds, and ruins of rocks [c].

DESCRIPTION, *&c.*

Root perennial. Stems ſeveral, ſhrubby, upright, looſe, branched at top, a fathom in height, the thickneſs of a finger or thumb. Branches covered with the ſheaths of the leaves, flexuoſe, leafy at top. Leaves ſuperdecompound, ternate. Leaflets ſubſeſſile, ovate, ſetaceous-acuminate, quite entire with a reflex margin, ſmooth. Petioles grooved, ſmooth. Flowers terminating, panicled. Panicle ſuperdecompound. Peduncles and pedicels angular [d]. Berry ſuperior, the ſize of a Pea, coriaceous, terminated by the ſhort ſtyle and the headed three-lobed ſtigma, red on the outſide turning to a ruſeſcent bay colour, covered with a white membrane within and one-celled. Seeds two, meniſcoid or concavo-convex, round, marked on one edge with a depreſſed ſtreak, running from the baſe to the tip, aſh-coloured or ruſeſcent. Sometimes only one ſeed comes to perfection, and then the other adheres to its baſe like a withered ſcale, the perfect ſeed retaining its meniſcoid form: but ſometimes the ſeeds have an excavation on each ſide [e].

Native of Japan, where it is generally cultivated in their gardens, flowering in may and june [f].

DESCRIPTIONS, *&c.*

1. Root perennial, frequently creeping. Stems ſmooth, about four feet high. Leaves alternate, upon pretty long ſlender foot-ſtalks, deeply cut into three lobes, which end in acute points, and are regularly ſerrate; thoſe on the lower part of the ſtem are near four inches long, and almoſt as much in breadth, but they diminiſh gradually to the top of the ſtem. At the baſe of the leaf comes out the peduncle, about three inches long, dividing at top into three ſmaller, each ſuſtaining one white flower, ſmaller than in the ſecond ſort, with a longer column of ſtamens, the anthers ſtanding out beyond the corolla.

[Linneus ſays, that the leaves are cordate, five-lobed, acuminate, flat; and that the peduncles have three or four flowers.]

2. Root perennial, compoſed of many thick fleſhy fibres, ſtriking deep into the ground, and connected at the top into a large head, from which come out many rough hairy leaves, near a foot diameter each way, deeply cut into ſix or ſeven lobes, irregularly indented on their edges, each lobe having a ſtrong midrib, all meeting at the foot-ſtalk, which is large and long, ariſing immediately from the root. Flower-ſtalks ſeven or eight feet high, dividing into ſmaller branches, having one leaf at each joint, of the ſame form as thoſe below, but diminiſhing in ſize towards the top, where they ſeldom have more than three lobes, which are divided to the foot-ſtalk. Towards the upper part of the ſtalk comes out from the ſide at each joint a long peduncle, branching out towards the top, and ſuſtaining ſeveral white flowers, which are tubulous at bottom where the ſegments of the petal are connected, but ſpread open above, and are divided into five obtuſe ſegments. The male plants are barren; but in the female plants the flowers are ſucceeded by [ten capſules, placed in a ring, ſemicircular, finiſhing at top in a recurved dagger-point, compreſſed wedge-ſhaped, convex on the back, with a raiſed line along the middle, flat at the ſides and ſubcrenulate towards the dorſal margin, one-celled, valveleſs, or ſometimes but ſeldom opening by two valves. Common receptacle central, pyramidal, grooved and finiſhing in a dagger-point: proper none or very ſhort. Seeds ſolitary, kidney-form, triangular-compreſſed, brown, very obſcurely ſtriated. Integument triple; the outmoſt very thin, the middle cartilaginous; the inmoſt membranaceous[a].

The female flowers have ſtamens, but the anthers are very ſmall, effete and barren. The leaves are ſubpeltate, but open to the very petiole and wrinkled; they have from two to ſeven lobes. Flowers in heads. Fruit orbicular, depreſſed, conſiſting of eight or ten joints[b].

Schreber, following Cavanilles, has united theſe plants to Sida, to which they are very nearly allied. But we may thus, as has been before remarked, thruſt all the plants of every natural order into one genus. Beſides the circumſtance of having fertile and barren hermaphrodite flowers on diſtinct individuals, the petals are not oblique, the pedicel is not jointed, and the calyx is wider at the baſe[c]. Gærtner remarks, that Napæa differs from Sida in having more than one capſule, and a manifeſt common receptacle; from Abutilon in having only one ſeed in each capſule, and that not clearly valved.]

Both theſe plants grow naturally in Virginia and other parts of North America. From their bark a ſort of hemp might be procured, ſuch as many of the malvaceous tribe afford. They flower from july to ſeptember, the ſeeds ripen in autumn, and then the ſtalks decay.

[Mr. Miller cultivated them in 1759[a].]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by ſeeds, ſown on a bed of common earth in the ſpring. Keep them clear from weeds till autumn, and then tranſplant them where they are to remain. They delight in a rich moiſt ſoil, in which they will grow very luxuriantly, and muſt be allowed room. The firſt ſort may alſo be increaſed by parting the roots in autumn. They are not plants of any great beauty.

β. Flore pleno. *Double Jonquill.*

Spathe many-flowered, nectary bell-ſhaped ſhort, leaves awl-ſhaped.

DESCRIPTIONS, *&c.*

1. The White Narciſſus has a ſmaller and rounder bulb than the common Daffodil. The leaves are longer, narrower and flatter. The ſtalk or ſcape does not riſe higher than the leaves, which are of a gray colour. At the top of the ſtalk comes out one flower from the ſpathe, nodding on one ſide. Corolla ſnow white, ſpreading open flat, the petals rounded at the points. The nectary or cup in the centre is very ſhort, and fringed on the border with a bright purple circle. The flowers have an agreeable odour, appear in may, and ſeldom produce ſeeds. The double white Narciſſus is a variety of this.

[The leaves are rounded on the keel, and reflected at the edge[1]. Villars remarks, that in moiſt mountain paſtures the roots come in bundles, producing a conſiderable packet of narrow erect leaves of an aſh-coloured green colour. The ſcape bears one flower, ſeldom two, hanging down, ſpreading, compoſed of ſix lanceolate petals ſeparate from each other, and having a little red (crimſon) circle in the middle, waved or fringed.

Curtis makes two varieties of this; the common one deſcribed above, which he calls *anguſtifolius*, flowering in april, and the *majalis*, flowering ſix weeks later.

It is a native of Italy, the South of France, Switzerland, and Carniola. Said alſo to be found wild in England on ſandy heaths, as at Shorne between Graveſend and Rocheſter: at Wood Baſtwick and other places in Norfolk[m].

It was cultivated here in 1570, as appears from Lobel[n].

From the deſcriptions of Theophraſtus, Dioſcorides and Pliny, there is little doubt of this ſpecies being the Narciſſus of thoſe authors and of the poets. The next ſpecies, if it be really diſtinct, was probably not conſidered as a ſeparate ſpecies by the ancients, ſince Ovid deſcribes his Narciſſus to have a yellow cup; whereas Dioſcorides makes it purple, and Pliny ſometimes one, ſometimes the other[o].

2. The pale Daffodil or Primroſe peerleſs, as it is called by our old authors, uſually produces two flowers, it frequently occurs however with one, more rarely with three, in a high ſtate of culture it probably may be found with more. When it has only one flower it may eaſily be miſtaken for one of the varieties of the preceding, which Mr. Curtis calls *majalis*; but it may be thus diſtinguiſhed from it: the petals are of a yelloviſh hue, or rather a pale cream colour; the nectary is wholly yellow, not having the orange or crimſon rim; and it flowers at leaſt three weeks earlier; the top alſo of the flowering ſtem in this, very ſoon after it emerges from the ground, bends down and becomes elbowed; whereas in the *majalis* it continues upright till within a ſhort time of the flowers expanding[p].

Native of ſeveral parts of Europe. Gerarde ſays that it grows wild in fields and by the ſides of woods in the weſt of England. Cluſius alſo reports that he had been credibly informed of its being a native of England. Ray had ſometimes obſerved it wild, but ſuſpected that it might have originally come out of gardens. James Sherard, M. D. found it near Hornſey-church; Mr. Blackſtone in ſeveral places near Harefield; Mr. Vernon at Bellow-hill near Whitchurch, Cheſhire; Mr. Wood near Halifax. It flowers towards the end of april.

β. Mr. Curtis has figured a Narciſſus under the name of M. tenuior, which ſeems to be ſcarcely a diſtinct ſpecies, though it has only one flower on the ſcape. The root is the ſize of a ſmall nutmeg, of a pale brown colour. Leaves about a ſpan long, very narrow, at their baſe ſcarcely a quarter of an inch wide, tapering gradually to a point, which is ſomewhat obtuſe, the outer ſide is convex and ſomewhat fluted, the inner concave, not glaucous. Stalk ſomewhat longer than the leaves, round, ſlightly flattened, eſpecially on its upper part, ſupporting on its ſummit one flower, of a fragrance leſs powerful than that of the Jonquill, and more ſo than that of *odorus*. Spathe membranous, length of the pedunicle, which is about an inch long. Flower, when fully blown, ſtanding horizontally; tube greenith, nearly cylindrical, ſomewhat longer than the pedunicle; border flat, divided into ſix ſegments, of a pale yellow or ſulphur colour, ovate, three alternate ſegments larger, each terminating in a ſhort dagger-point. Nectary yellow, in form like that of N. biflorus, plaited, the margin, as the flower declines becoming brown. Anthers of the three longer ſtamens viſible in the mouth of it.

Mr. Curtis firſt obſerved this Narciſſus in the month of may 1794, in a ſingle, but moſtly in a double ſtate, in the garden of Mr. James Maddock, florift at Walworth, who obtained it from Holland. It appears to have been long cultivated by the Dutch, and from its hardineſs is probably of European origin. It is inferior in ſize and beauty to many others; but as a ſpecies Mr. Curtis thinks it very diſtinct.] Mr. Miller alſo has a variety, which he names *N. albus*, n. 5. the petals, he ſays, are whiter and reflexed; the border of the cup is gold-coloured.

3. Common Engliſh Daffodil has a large bulbous root, from which come out five or ſix flat leaves, about a foot long, and an inch broad, of a grayiſh colour, and a little hollow in the middle like the keel of a boat. The ſtalk riſes a foot and half high, having two ſharp longitudinal angles; at the top comes out one nodding flower, incloſed in a thin ſpathe. The corolla is of one petal, being connected at the baſe, but cut almoſt to the bottom into ſix ſpreading parts; in the middle is a bell-ſhaped nectary, called by gardeners the cup, which is equal in length to the petal and ſtands erect. The petal is of a pale brimſtone or ſtraw colour, and the nectary is of a full yellow. Seeds roundiſh, black.

[The ſcape is a little longer than the leaves. Petals ovate-lanceolate, the three outer longer and narrower than the three inner. The rim of the nectary is a little plaited and ſnipt. Germ three-ſided. Seeds kidney-form, rough[s].

Native of many parts of Europe; Spain, Italy, Germany, Switzerland, France, England, in paſtures, woods and hedges; flowering in march. Near Charlton, Woolwich and Erith in Kent; in Norfolk; Whitwell near Caton, and Whittleſford in Cambridgeſhire; Noke woods in Oxfordſhire; about Halifax very abundantly; in Lancaſhire; Hanley Caſtle in Worceſterſhire; Malely in Shropſhire; about Sutton Coſield, and beyond Erdington on the road from Birmingham to Sutton, it covers almoſt a whole field.]

Varieties are

1. With white petals and a pale yellow cup,
2. With yellow petals and a golden cup.

[1] Engl. bot. [m] Withering and Engl. bot. [n] Hort. kew. [o] Virg. Georg. 4. 122. ed. Mart. note. [p] Curtis. [s] Haller, Krocker, Withering.

3. With a double flower.
4. With three or four cups within each other.
5. Tradescant's Daffodil.
[6. Peerless Daffodil.

Parkinson has many varieties, as

1. Pseudonarcissus anglicus flore pleno, or Gerarde's double Daffodil; he having first discovered it in a poor woman's garden in the west of England: it is said to be natural in the Isle of Wight[1]. This circumstance is not mentioned in Gerarde's herbal. He there says that he received the double yellow Daffodill from Robinus of Paris.
2. Pseudonarcissus aureus maximus flore pleno, f. roseus Tradescanti, or John Tradescant's great Rose Daffodill. The same with n. 5. above. This Prince of Daffodils, says Parkinson, belongeth primarily to John Tradescant, as the first founder thereof, and may well be entituled the Glory of Daffodils. The flower is very much spread open, consisting of smaller and shorter leaves than the next, but more in number, thicker and rounder set together, making it seem as great and double as any Provence Rose, and intermixt with divers yellow and pale leaves, as if it were in rows one under another. It abideth long in flower, and spreadeth to be the broadest in compass of any of the Daffodils[2].
3. Pseudonarcissus aureus anglicus maximus, or Wilmer's great double Daffodil. This differs from the common sort (n. 1.) only in the largeness of the leaves and flowers, and the stateliness of growth. The stalk is two feet high, the flower great and fair, each leaf of it twice as large and broad as the former, diversely intermixt with a row of paler and of deeper yellow leaves, both growing deeper by standing. This we had from Vincent Sion, born in Flanders, dwelling on the Bank side, an industrious and worthy lover of fair flowers, who cherished it in his garden for many years until the year 1620, when it flowered, and he shewed it to Mr. John de Franqueville, of whom he supposed he received it; who finding it to be a kind never known to us before, caused him to respect it the more, as it is well worthy. And George Wilmer, of Stratford Bow, Esq. having likewise received it of him, as myself did also, would needs appropriate it to himself, and call it by his own name, which since hath so continued[3].
4. Narcissus latifolius omnium maximus amplo calice flavo, five Nompareille. The great Nonesuch or Incomparable Daffodill. Stalk two feet high at the least. Flower large, single, consisting of six very pale yellow large leaves, almost round at the point, with a large cup in the middle somewhat yellower, the bottom whereof is narrow and round, rising wider to the mouth, which is very large and open, unevenly cut in or indented about the edges; this cup doth well resemble the chalice, that in former days with us, and beyond the seas is still used to hold the Sacramental Wine. The flower hath sometimes ten or twelve leaves, and a cup much larger.

Narcissus omnium maximus flore & calice flavo. The great yellow Incomparable Daffodill. This differs neither in form, nor bigness of leaf or flower from the former; but in the colour of the circling leaves of the flower, which are of the same yellow colour with the cup. This sometimes brings two flowers upon a stalk distinct, and sometimes two flowers almost together, as if they were but one[4].]

Mr. Miller considers this as a species distinct from our common Daffodil; from which it differs in having longer leaves, of a darker green, and higher flower-stalks; the segments of the petal also are rounder, and spread open flatter; the cup is about half the length of the petal, and is edged with a gold-coloured fringe. It flowers in april; and varies more than any other.

The roots, the first year, produced very double flowers; the six outer segments longer than the others and white, the middle very full of shorter petals, some white others yellow, collected into a globular figure. Some of these roots, the following year, produced flowers less double, with no white petals, but the largest petals sulphur-coloured, and the others yellow. From this they afterwards degenerated to half-double flowers; and at last to single flowers, with a cup half the length of the petal, in which manner they continued to flower many years: we may conclude therefore that the last was the natural state of the flower. [In this state Mr. Curtis has figured it as a distinct species. He says, that the petals are usually pale yellow, and the nectary inclining to orange, which towards the brim is more brilliant in some than in others. In its double state it is well known to gardeners by the name of Butter and Egg Narcissus; and of this there are two varieties, one with colours like the single one above-mentioned, the other with petals of a pale sulphur colour, almost white, and the nectary bright orange, which is named in the Dutch catalogues *Orange Phœnix*, is the most ornamental among the several varieties, and has flowers so large as frequently to require support. If the bulbs be not taken up yearly, they will degenerate as Mr. Miller represents.] He received roots of it from Spain and Portugal.

[Parkinson enumerates other varieties, as

5. Narcissus maximus griseus calice flavo. The peerless gray Daffodill: which has the six outer leaves of the flower of a glistering whitish gray colour, and the cup yellow, longer than that of the preceding.
6. Narcissus latifolius, flavo flore, amplo calice. The lesser yellow Nonpareille or the Lady Matteoffes Daffodill, by which name it was known in the Low Countries, Clusius having received it from her.—The leaves of this are shorter and narrower, the stalk not so high, the flower smaller, the cup and petals both pale yellow, yet more yellow than in the former, the cup smaller, and neither so small in the bottom, nor so large at the edges, nor so crumpled at the brims[5].

But of these varieties enough.

4. This resembles the Common Daffodil, but the petals are white, the nectary is dark yellow and larger, with a spreading, waved, notched border[6]. Gouan says it is easily distinguished by its leaves scarce a palm in length and half an inch in breadth; by its large flower, with cordate-ovate petals, imbricate at the base, and sulphur-coloured; and by the nectary having a reflex mouth, twelve-cleft or thereabouts, the lobes also being toothed and curled: the scape is the length of the leaves, or a little shorter, and thick.

Native of the South of Europe, flowering in april and may. Cultivated in 1629 by Parkinson[7].

β. This is the largest of the genus, and bears the most magnificent flowers: though it has long been known in this country, it is confined to the gardens of the curious. It approaches in its general appearance very near to the Common Daffodil, but it is a much taller plant, and has its leaves more twisted, as well as more glaucous: the flower, but especially the nectary, is much larger, and the petals are more spreading. It answers to the *bicolor* of Linnæus in every respect but colour, which is always a fine deep yellow. It varies with double flowers. It is a native of Spain, and flowers with us in april. Parkinson calls it the great yellow Spanish bastard Daffodill[8].

5. The Little Daffodil is nearly related to the Common sort, but is three times smaller in all its parts: the scape is scarcely striated: the spathe is greenish: the flowers more nodding: the petals distinct at the base, lanceolate, straight, not oblique or ovate: margin of the nectary six-cleft, waved, curled[9].

Though the flowers are not so large as those of the other species, yet when the roots are planted in a cluster, they make a very pretty show, and have this advantage, that they flower somewhat earlier than any of the others[10].

Native of Spain. Cultivated in 1629, according to Parkinson[11].

6. Nectary cylindric, with the mouth obscurely repand, neither toothed nor curled.—Native of Spain.

[1] Park. parad. 103. [2] 102. n. 1. [3] 102. n. 2. & 104. [4] Parad. p. 68. 1. 2. [5] Parad. p. 69. [6] Linn. spec. [7] Hort. kew. [8] Curtis. [9] Linn. spec. [10] Curtis. [11] Hort. kew.

7. This is of the same size with N. poeticus, but the leaves are narrower by half and channelled. Spathe one-flowered. The whole corolla snow-white. Petals ovate-oblong. Nectary bell-shaped, shorter by half than the corolla, with the margin straight, and unequally crenulate. Stamens three, seldom six. Anthers dark yellow, shorter than the nectary [a].

The N. triandrus of our nurseries near London is pale yellow, Mr. Curtis's figure has two flowers from a spathe, there are constantly six stamens, three reaching no farther than the mouth of the tube [b].

Parkinson's figure has three flowers from a spathe. He describes it as having three, four or more snow white flowers, standing upon long green footstalks, every flower hanging down his head, and turning up his six narrow and long leaves, even to the very footstalk again: from the middle of the flower hangeth down a long round cup, as white as the leaves, within which are contained three small white chives tipt with yellow, and a small long pointell, thrusting out beyond the brims of the cup.

Parkinson has described several others with reflexed petals, probably varieties of this. One wholly of a gold colour, both cup and petals. A second yellow with a white cup. A third white with a yellow cup [c].

Linnæus makes it native of the Pyrenees, in which he is followed by Mr. Curtis: according to the Kew catalogue, it is from Portugal. Clusius says that a French herbarist, named Nicolas le Quet or Quilt, who searched the Pyrenees and Spain every year, introduced it in 1599. It was cultivated in England in 1629, as appears from Parkinson [d]. It seems afterwards to have been lost, and to have been re-introduced lately [e].

8. This is a broad-leaved species, having the appearance of N. Tazetta. Corolla white. Nectary erect, half or one-third of the length of the petals, trifid, yellow with the lobes emarginate [f]. Of this there are several varieties.

Native of the Levant. Cultivated in 1758 by Mr. Miller. It flowers in may [g].

9. This resembles N. Jonquilla, but the nectary is cylindric, more than half the length of the petals, not cutted, but obscurely three-lobed.—Native of the South of Europe [h].

10. Flower deep yellow, three times as large as that of N. Tazetta, sometimes one only from a spathe, sometimes more: nectary not fringed, but divided at the mouth into six blunt lobes [i].

Parkinson says, it bears two or three very fair large flowers, with a large and more open cup, than any other of the Rush Daffodils, both of a fair yellow colour, yet the cup a little deeper, and a little crumpled about the edges.

This species, which, as its name implies, possesses more fragrance than many of the others, is a native of the South of Europe, flowers in april, and varies with double flowers. Mr. Miller takes no notice of it, except merely as a variety of N. Jonquilla [k]. He cultivated it in 1758. It flowers in april and may [l].

11. This resembles N. Tazetta very much, but the petals are a little larger and sharper: the nectary is the same length with the petals [m].

Leaves two or three, a foot or more in length. Stem slender, strong, a foot in length. Flowers two or three from a spathe, very elegant, large and loose: petals yellow: cup half an inch long, situated at the edge, of a deeper yellow colour. It has the odour of the Jonquil [n].

Clusius first observed this in flower in april 1593, in the garden of Theodoric Clutius or Cluyts, prefect of the Academic Garden at Leyden: both Cluyts and Cornelius van Hille, a minister at Rotterdam, gave him bulbs of it.—Native of the South of Europe and the Levant.

12. Bulbs large, roundish. Leaves three or four, long, narrow, plane. Scape or flower-stalk upright, broadish; angular, concave, from ten or twelve to eighteen inches in height. Flowers six or seven to ten from one spathe, very fragrant, clustered, white or yellow.

Native of Spain and Portugal, the South of France, Italy and Japan; Mr. Miller adds the islands of the Archipelago, and Parkinson the neighbourhood of Constantinople. Clusius observed it at the end of january 1565 in Spain and Portugal, and at the beginning of february at Gibraltar. Ray found it in Italy between Leriei and Massa and between Massa and Lucca, in april: also about Montpelier in february and march.]

There is a greater variety of the Polyanthus Narcissus than of all the other species; for the flowers being very ornamental and coming early in the spring, the florists in Holland, Flanders and France have taken great pains in cultivating and improving them.

The principal varieties are these:

1. Petals yellow, with orange, yellow, or sulphur-coloured cups or nectaries.
2. Petals white, with orange, yellow or sulphur-coloured cups or nectaries.
3. Petals white, with white cups or nectaries.
4. Double flowers of the different varieties.

[The Dutch and London Catalogues contain about an hundred subvarieties under these heads, with pompous names, which are too subject to the light breath of fashion and caprice to be enumerated here.]

The varieties with white petals and white cups are not so much esteemed as the others; there are however two or three with large bunches of small white flowers, which are valuable for their agreeable odour, and for flowering later than most of the others. There is also one with very double flowers, the outer petals white, those in the middle some white, others orange-coloured. This has a very agreeable scent, flowers early, and is generally called the Cyprus Narcissus. It is the most beautiful of all the varieties, when blown in glasses in a room.

[Gerarde describes and figures this variety under the name of Narcissus albus polyanthos, or double white Daffodil of Constantinople, whence he says it was sent into England unto the right honorable the Lord Treasurer among other bulbed flowers.]

13. Bulbs small. Leaves very narrow, having some resemblance to those of the Rush, but a little compressed, with a longitudinal furrow on one side, they are seldom more than eight or nine inches long. Flower-stalk slender, taper, about six inches long: petal scarce half an inch long, cut into six acute segments; the nectary or cup is more than two inches long, very broad at the brim, lessening gradually to the base, formed somewhat like the old farthingale or bell-hoop petticoat worn by the ladies. It is a native of Portugal, whence Mr. Miller received the roots. [but it was also cultivated in the time of Parkinson [o], though now amid the multitude of novelties that flow in upon us from every quarter it is not common in our flower-borders. Mr. Curtis informs us that he has seen it grow abundantly in some gardens in Hampshire. It flowers in april or may.]

14. Bulb small. Leaves few, narrow. Stalk jointed, nine inches high. Corolla white, cut into six narrow segments: cup yellow. It flowers late in the autumn. Native of Spain, Italy and Barbary. Cultivated by Mr. Miller before 1759.

15. The Jonquil from the narrowness of its leaves, like those of Rushes, has its name, and is called by old authors *Narcissus juncifolius*: there are two or three of them usually on a plant, and they are angular, fleshy and almost round. Scape round, hollow, producing at top from three to five flowers from a spathe, sometimes no more than two, very fragrant petals orbiculate or mucronate, both they and the cup yellow. Bulb small, white, covered with dark membranes [p]. Native of Spain. Cultivated by Gerarde in 1597. It flowers in april and may, and varies with double flowers [q].]

PROPAGATION AND CULTURE.

1 to 7, &c. All the hardy sorts of Daffodil and Narcissus may be planted in large borders of the flower garden, where being intermixed with other bulbs they

afford

afford an agreeable variety. They will thrive in almoſt any ſoil or ſituation, and even under the ſhade of trees, where they will produce annually in the ſpring great quantities of flowers for ſeveral years together without tranſplanting, and make a good appearance before the trees come out in leaf.

[They increaſe abundantly by offsets. The double ſorts ſhould be taken up yearly, to prevent their becoming ſingle.]

12. I ſhall firſt treat of the method for raiſing the fine ſorts of Polyanthus Narciſſus from ſeeds, which is the way to obtain new varieties.

The not practiſing this has occaſioned our ſending abroad annually for great quantities of flower-roots, which have been kept up to a high price, on account of the great demand for them in England; whereas if we were as induſtrious to propagate them as our neighbours, we might ſoon vie with them, if not outdo them, in moſt ſorts of flowers, as may be ſeen, by the vaſt variety of Carnations, Auriculas, Ranunculas, &c. which have been produced from ſeeds in England, and exceed moſt of thoſe kinds in any part of Europe.

You muſt be very careful in ſaving your ſeeds, to gather none but from ſuch flowers as have good properties, and particularly from ſuch only as have many flowers upon a ſtalk, that flower tall, and have beautiful cups to their flowers; from ſuch you may expect to have good flowers produced; but if you ſow ordinary ſeed, it is only putting yourſelf to trouble and expenſe to no purpoſe, ſince from ſuch ſeeds there can be no hopes of procuring any valuable flowers.

Having provided yourſelf with good ſeeds, you muſt procure either ſome ſhallow caſes or flat pans, made on purpoſe for the raiſing of ſeedlings, which ſhould have holes in their bottoms, to let the moiſture paſs off; theſe muſt be filled with freſh, light, ſandy earth about the beginning of auguſt (that being the ſeaſon for ſowing the ſeeds of moſt bulbous-rooted flowers;) the earth in theſe muſt be levelled very even; then ſow the ſeeds thereon pretty thick, covering them over with fine ſifted light earth about half an inch thick, and place the caſes or pans in a ſituation where they may have only the morning ſun till about ten o'clock, where they ſhould remain until the beginning of october, when they muſt be removed into a warmer ſituation, placing them upon bricks, that the air may freely paſs under the caſes, which will preſerve them from being too moiſt.

They ſhould alſo be expoſed to the full ſun, but ſcreened from the north and eaſt winds; and if the froſt ſhould be ſevere, they muſt be covered, otherwiſe there will be danger of their being deſtroyed; in this ſituation they may remain until the beginning of april, by which time the plants will be up, when you muſt carefully clear them from weeds: and if the ſeaſon ſhould prove dry, they muſt be frequently watered: the caſes ſhould alſo now be removed into their former ſhady poſition, or ſhaded in the middle of the day, for the heat of the noon-day ſun will be too great for the young plants.

The latter end of june, when the leaves of the plants are decayed, you ſhould take off the upper ſurface of the earth in the caſes (which by that time will have contracted a moſſineſs, and, if ſuffered to remain, will greatly injure the young roots) obſerving not to take it ſo deep as to touch the roots; then ſift ſome freſh light earth over the ſurface, about half an inch thick, which will greatly ſtrengthen the roots: the ſame ſhould alſo be repeated in october, when the caſes are moved again into the ſun.

During the ſummer ſeaſon, if the weather ſhould prove very wet, and the earth in the caſe appear very moiſt, you muſt remove them into the ſun till the earth be dry again; for if the roots receive much wet during the time they are inactive, it very often rots them; therefore you muſt never give them any water after their leaves are decayed, but only place them in the ſhade, as was before directed.

Thus you ſhould manage them the two firſt ſeaſons, till their leaves are decayed; but the ſecond ſummer after ſowing, you ſhould carefully take up the roots; which may be done, by ſifting the earth in the caſes through a fine ſieve, whereby the roots will be eaſily ſeparated from the earth; then having prepared a bed or two of good freſh light earth, in proportion to the quantity of your roots, you ſhould plant them therein, at about three inches diſtance every way, and about three inches deep in the ground.

Theſe beds ſhould be raiſed above the level of the ground, in proportion to the moiſture of the ſoil, which if dry, three inches will be enough; but if it be wet, they muſt be raiſed ſix or eight inches high, and laid a little rounding, to ſhoot off the wet.

If theſe beds are made in july, which is the beſt time to tranſplant the roots, the weeds will ſoon appear very thick; therefore you ſhould gently hoe the ſurface of the ground to deſtroy them, being very careful not to cut ſo deep as to touch any of the roots; and this ſhould be repeated as often as may be found neceſſary, by the growth of the weeds, obſerving always to do it in dry weather, that they may be effectually deſtroyed; and toward the latter end of october, after having entirely cleared the beds from weeds, you ſhould ſift a little rich light earth over them, about an inch thick; the goodneſs of which will be waſhed down to the roots by the winter's rain, which will greatly encourage their ſhooting in the ſpring.

If the cold ſhould be very ſevere in winter, you ſhould cover the beds either with old tan or ſea-coal aſhes, or in want of theſe with Peaſe-haulm, or ſome ſuch light covering, to prevent the froſt from penetrating the ground to the roots, which might greatly injure them while they are ſo young.

In the ſpring, when the plants begin to appear above ground, you muſt gently ſtir the ſurface of the ground, clearing it from weeds, &c. in doing of which, you ſhould be very careful not to injure the plants; and if the ſeaſon ſhould prove dry, you ſhould now and then gently refreſh them with water, which will ſtrengthen the roots.

When their leaves are decayed, you ſhould clear the beds from weeds, and ſift a little earth over them (as was before directed) which muſt alſo be repeated in october, in like manner; but the roots ſhould not remain longer in theſe beds than two years, by which time they will have grown ſo large as to require more room; therefore they ſhould be taken up as ſoon as their leaves are decayed, and planted into freſh beds, which ſhould be dug deep, and a little very rotten dung buried in the bottom, for the fibres of the roots to ſtrike into. Then the roots ſhould be planted at ſix inches diſtance, and the ſame depth in the ground.

In the autumn, before the froſt comes on, if ſome rotten tan is laid over the beds, it will keep out the froſt, and greatly encourage the roots; and if the winter ſhould prove ſevere, it will be proper to lay a greater thickneſs of tan over the beds, and alſo in the alleys, to keep out froſt, or to cover them over with ſtraw, or peaſe-haulm, otherwiſe they may be all deſtroyed by the cold. In the ſpring theſe coverings ſhould be removed, as ſoon as the danger of hard froſt is over, and the beds muſt be kept clean from weeds the following ſummer: at Michaelmas they ſhould have ſome freſh earth laid over the beds, and covered again with tan, and ſo every year continued till the roots flower, which is generally in five years from ſeed, when you ſhould mark all ſuch as promiſe well, which ſhould be taken up as ſoon as their leaves decay, and planted at a greater diſtance in new prepared beds; but thoſe which do not flower, or thoſe you do not greatly eſteem, ſhould be permitted to remain in the ſame bed; therefore, in taking up thoſe roots which you marked, you muſt be careful not to diſturb the roots of thoſe left, and alſo to level the earth again, and ſift ſome freſh earth over the beds (as before) to encourage the roots; for it often happens in the ſeedlings of theſe flowers, that at their firſt time of blowing, their flowers ſeldom appear half ſo beautiful as they do the ſecond year; for which reaſon none of them ſhould be rejected until they have flowered two or three times, that ſo you may be aſſured of their worth.

Thus having laid down directions for the ſowing and managing theſe roots, until they are ſtrong enough to flower,

flower, I ſhall proceed to give ſome inſtructions for planting and managing the roots afterwards, ſo as to cauſe them to produce large fair flowers.

All the ſorts of Narciſſus which produce many flowers upon a ſtalk, ſhould have a ſituation defended from cold and ſtrong winds, otherwiſe they will be ſubject to be injured by the cold in winter, and their ſtems broken down when in flower; for notwithſtanding their ſtalks are generally pretty ſtrong, yet the number of flowers upon each renders their heads weighty, eſpecially after rain, which lodges in the flowers, and, if ſucceeded by ſtrong winds, very often deſtroys their beauty, if they are expoſed thereto; ſo that a border under a hedge, which is open to the ſouth-eaſt, is preferable to any other poſition for theſe flowers.

The morning ſun riſing upon them will dry off the moiſture which had lodged upon them the preceding night, and cauſe them to expand fairer than when they are planted in a ſhady ſituation; and if they are too much expoſed to the afternoon ſun, they will be hurried out of their beauty very ſoon; and the ſtrong winds uſually coming from the weſt and ſouth-weſt points, they will be expoſed to the fury of them, which frequently is very injurious to them.

Having made choice of a proper ſituation, you muſt then proceed to prepare the earth neceſſary to plant them in; for if the natural ſoil of the place be very ſtrong or poor, it will be proper to make the border of new earth, removing the former ſoil away about three feet deep. The beſt earth for theſe flowers is a freſh, light, hazel loam, mixed with a little very rotten neats dung: this ſhould be well mixed together, and often turned over, in order to ſweeten it; then having removed away the old earth to the fore-mentioned depth, you ſhould put a layer of rotten dung or tan in the bottom, about four or five inches thick, upon which you muſt lay ſome of the prepared earth about eighteen or twenty inches thick, making it exactly level; then having marked out by line the exact diſtances at which the roots are to be planted (which ſhould not be leſs than ſix or eight inches ſquare) you muſt place the roots accordingly, obſerving to ſet them upright; then you muſt cover them over with the before-mentioned earth about eight inches deep, being very careful in doing it, not to diſplace the roots; when this is done, you muſt make the ſurface of the border even, and make up the ſide ſtraight, which will appear handſome.

The beſt time for planting theſe roots is in the end of auguſt, or beginning of ſeptember; for if they are kept too long out of the ground, it will cauſe their flowers to be weak. You ſhould alſo obſerve the nature of the ſoil where they are planted, and whether the ſituation be wet or dry, according to which you ſhould adapt the freſh earth, and order the beds; for if the ſoil be very ſtrong and the ſituation moiſt, you ſhould then make choice of a light earth, and raiſe the beds ſix or eight inches, or a foot, above the level of the ground, otherwiſe the roots will be in danger of periſhing by too much wet; but if the ſituation be dry and the ſoil naturally light, you ſhould then allow the earth to be a little ſtronger, and the beds ſhould not be raiſed above three or four inches high; for if they are made too high, the roots will ſuffer very much, if the ſpring ſhould prove dry, nor would the flowers be near ſo fair. As alſo in very ſevere winters, theſe beds which are raiſed much above the level of the ground, will be more expoſed to the cold than thoſe which are lower, unleſs the alleys are filled up with rotten tan or litter.

During the ſummer, the only culture theſe flowers require is, to keep them free from weeds; and when their leaves are entirely decayed, they ſhould be raked off, and the beds made clean: but by no means cut off their leaves till they are quite decayed, as it is by ſome practiſed, for that greatly weakens the roots.

Towards the middle of october, if the weeds have grown upon the beds, you ſhould in a dry day gently hoe the ſurface of the ground to deſtroy them, obſerving to take it over ſmooth again; and before the froſts come on, the beds ſhould be covered over two inches thick with rotten tan, to keep out the froſt: after which they will require no farther care till the ſpring, when their leaves will appear above ground; at which time you ſhould gently ſtir the ſurface of the earth with a ſmall trowel, being very careful not to injure the leaves of the plants, and rake it ſmooth with your hands, clearing off all weeds, &c. which, if ſuffered to remain at that ſeaſon, will ſoon grow ſo faſt as to appear unſightly, and will exhauſt the nouriſhment from the earth. With this management theſe roots will flower very ſtrong, ſome of which will appear in march, and the others in april, which, if ſuffered to remain, will continue in beauty a full month, and are, at that ſeaſon, very great ornaments to a flower-garden.

After the flowers are paſt, and the leaves decayed, you ſhould ſtir the ſurface of the ground, to prevent the weeds from growing; and if at the ſame time you lay a little very rotten dung over the ſurface of the beds, the rain will waſh down the ſalts thereof, which will greatly encourage the roots the ſucceeding year.

During the ſummer ſeaſon they will require no farther care, but to keep them clear from weeds till october, when the ſurface of the beds ſhould be again ſtirred, raking off all weeds, &c. and laying ſome good freſh earth over the beds about an inch deep, which will make good the loſs ſuſtained by weeding, &c. and in the ſpring you muſt manage as was directed for the preceding year.

Theſe roots ſhould not be tranſplanted oftener than every third year, if they are expected to flower ſtrong and make a great increaſe; becauſe the firſt year after removing, they never flower ſo ſtrong as they do the ſecond and third; nor will the roots increaſe ſo faſt, when they are often tranſplanted, but if you let them remain longer than three years unremoved, the number of offſets which by that time will be produced, will weaken the large bulbs, and cauſe them to produce very weak flowers; therefore at the time of tranſplanting them, all the ſmall offſets ſhould be taken off, and planted in a nurſery-bed by themſelves, but the large bulbs may be planted again for flowering. If you plant them in the ſame bed where they grew before, you muſt take out all the earth two feet deep, and fill it up again with freſh, in the manner before directed, which will be equal to removing them into another place: this is the conſtant practice of the gardeners in Holland, who have but little room to change their roots, therefore they every year remove the earth of their beds, and put in freſh, ſo that the ſame place is conſtantly occupied by the like flowers. But thoſe people take up their roots every year, for as they cultivate them for ſale, the rounder their roots are, the more valuable they will be: the way to have them ſo is, to take their offſets from them annually; for when their roots are left two or three years unremoved, the offſets will have grown large, and theſe preſſing againſt each other, will cauſe their ſides to be flatted; ſo that where the roots are propagated for ſale, they ſhould be annually taken up as ſoon as their leaves decay, and the large bulbs may be kept out of the ground till the middle or end of october, but the offſets ſhould be planted the beginning of ſeptember or ſooner, that they may get ſtrength, ſo as to become blowing roots the following year: but where they are deſigned for ornament, they ſhould not be removed oftener than every third year, for then the roots will be in large bunches, and a number of ſtalks with flowers coming from each bunch, they will make a much better appearance than where a ſingle ſtalk riſes from each root, which will be the caſe when the roots are annually removed.

[Perſons who are nice in theſe flowers, ſhelter them by an awning during the time of flowering to keep off ſun, rain and wind, as is practiſed with Auriculas, Carnations and other very handſome delicate flowers, to preſerve the beauty of the bloom, and to continue it longer. The Polyanthus-Narciſſus may be blown in glaſſes in rooms during the winter and early in the ſpring, from october to march.]

10, 11, 15. The Jonquils ſhould be planted in beds

or borders, separate from other roots, because these require to be transplanted at least every year, otherwise their roots are apt to grow long and slender, and seldom flower well after; which is also the case, if they are continued many years in the same soil; wherefore the roots should be often removed from one part of the garden to another, or at least, the earth should be often renewed, which is the most probable method to preserve their flowers in perfection.

The soil in which these flowers succeed best, is an hazel loam, neither too light nor over stiff; it must be fresh, and free from roots of trees or noxious weeds, but should not be dunged; for it is very remarkable, that where the ground is made rich, they seldom continue good very long, but are subject to shoot downwards, and form long slender roots.

These flowers are greatly esteemed by many people for their strong sweet scent, though there be very few ladies that can bear the smell of them, especially if confined in a room.

[Where the smell of the Jonquils can be endured, they are blown with success in glasses, as well as the Polyanthus Narcissus. The glasses should be filled up to the bottom of the bulb with fresh soft water: place them in a light warm room, near windows which have the benefit of the sun; and keep up the water to the same height, by putting in a fresh supply every fortnight or three weeks. These and other flowers may also be brought forward in a warm room in pots set in pans of water; or still more effectually in stoves or hot-beds, by which means a succession of these flowers may be obtained during the winter and spring till they appear in the natural ground.

Spike curved in ciliate.

DESCRIPTIONS, *&c.*

1. Root perennial. Culms from a span to a foot in height, slender, stiff, roughish, having one, two or three joints near the base, with a short leaf to each, and thence naked to the spike. Root-leaves numerous, longer, narrow, a little rough. Spike two or three inches long, consisting of about twenty spikelets dispersed thinly along the rachis. Florets yellowish white or purple, pubescent, alternate, sessile. Rachis or spike-stalk convex on one side, hollowed on the other, with rough alternate teeth on the edges for the insertion of the florets, and continued above them to a short bristly point [a].

This grass is easily distinguished by the slenderness and rushy stiffness of the stalks and leaves; and by the florets being thinly dispersed along the spike, mostly in pairs, pointing all the same way, and having each only one style. It flowers from may or june to august: Ray says from the end of april; and that it holds its spike till winter.—Native of most parts of Europe, in woody moist barren meadows; with us chiefly on or about bogs or heaths.

Being stiff, hard and short, Linneus observes that it eludes the stroke of the scythe, or takes off its edge, for which reasons it is disliked by the mowers. In England it rarely comes under the scythe.

Linneus also informs us that crows frequently stock it up, for the sake of the larva of some Tipula, which they find at the root. He says that goats and horses eat it, but that cows and sheep are not fond of it. With us it does not seem to be applied to any use.

Gerard remarks that the corolla is sometimes three-valved, the outer valve being shorter and performing the office of a calyx.

2. Root biennial. This is a very small species. The leaves curve back and roll up like hair, dry away and disappear in part. The spike makes about one-third of the culm: it is curved back at the end, which discovers the little awns of the florets, for they are so small that they are not seen without attention and practice. The florets come in pairs in a very small scale, which serves them for a calyx, and which might rank this grass with the Loliums. The florets are very slightly pedunclcd, two-valved, and terminated by a little awn.—Native of the South of Europe, in sandy barren soils.

3. This grass is the length of a finger, branched a little, and smooth. Leaves flat, shorter than the culm, alternate, remote. Spike imbricate, very narrow towards the flowers.—Found by Koenig, in Tranquebar in the East Indies [b].

4. Leaves flat. Culm a span high. Spike halved, or having only on one side, alternate erect florets, from twelve to fifteen in number; the outer valve ovate-oblong, awnless, ciliate along the edge with numerous rugged scales. Proper calyx none, but on one side of the florets a bristle, shorter than the glume [c].—Native of the East Indies.

Leaves oblong pointed, peduncles terminating solitary or in threes.

DESCRIPTIONS, *&c.*

1. This is a large tree, with a straight trunk, and spreading branches. Leaves quite entire, large, smooth, petioled, opposite, with thick, parallel, curved nerves. Flower on a long peduncle, composed of very many yellow florets gathered into a ball two inches in diameter. Proper perianth fleshy, unequally many-cleft. Corolla usually five-cleft, with as many stamens. Style very long, conglobate every way into a large hoary head, by their united force concealing the golden florets. Stigma entire, turbinate, acuminate. Fruit a berry compounded of the fleshy perianths of the florets, coalescing irregularly into a globular, lacunose body [a].

Gærtner describes it as a Capsule, inferior, small, turbinate, corticate, crowned with a callous ring the remains of the fallen flower, smooth, two-grained: rind coriaceous, opened at top by the gaping grains; which are cartilaginous, hard, whitish, convex on one side, slightly concave on the other, one-celled, opening elastically two ways at top. Receptacle triple: first, of the fructification globular; secondly, of the fruit filiform, between the grains, and inserted into their upper part, as in umbellate plants; thirdly, of the seed, a prominent nerve of the gaping future of the grains, by which the seeds hang. Seeds in each grain about sixteen, small, ovate, compressed a little, or somewhat angular, membranaceous-margined, attenuated at top into a bristle-shaped tail, ruiescent.

Native of the East Indies, Cochinchina, and the Society isles.

The wood is yellow, solid, beautiful and fit for all works within doors; exposed to air and wet it rots quickly [b].

2. Trunk straight, with a brownish-gray, cracked bark. Branches opposite, numerous, spreading, forming a large, oval, shady head. Leaves opposite, decussated, entire, smooth. Petiole channelled. Stipules large, oblong, obtuse, glutinous, falling. Peduncles single or three; when three, the middle one is shortest, near the apex jointed, and bracted, each supporting a single globular naked head of florets. Bractes two, opposite, near the extremity of the peduncle, oval, falling. Flowers small, light yellow. Receptacle chaffy: chaffs wedge-form, hairy at their insertions. Calyx very minute, entire. Divisions of the corolla pointed, spreading. Filaments inserted just within the mouth of the tube: anthers erect, oblong, pointed above. Style nearly twice the length of the corolla: stigma large resting on the style. Capsules turbinate, covered with a scabrous crust or bark, which splits irregularly when the seeds are ripe: within is the proper two-celled capsule, each consisting of one valve, opening round the apex, and down on the inside. Seeds several, very minute, oblong, tailed, inverse, imbricated round the outside of their receptacles with the insertion downwards.

This grows to a large tree, and is a native of almost every part of the coast of Coromandel, but chiefly among the mountains, flowering during the cold season. It is called Bota-cadamie by the Telingas.

The wood is of a light chestnut colour, firm and close grained. It is used for various purposes, where it can be kept dry; but if exposed to wet it soon rots.

3. Trunk erect. Bark like that of the preceding. Branches very numerous, horizontal, forming a very large shady head. Leaves opposite, decussated, pointed, entire, above pretty smooth, below downy, particularly when young, and beautifully netted with small veins; from four to twelve inches each way. Petiole round, a little downy, from two to three inches long. Stipules as in the preceding. Peduncles round, downy, the same length with the petioles, near the apex jointed and bracted, each supporting a single globular head. Bractes oval, falling. Flowers as in the preceding. Divisions of the calyx, and stigma clubbed. Capsule wedge-form. Seeds about six in each cell, surrounding their receptacle, oblong, not imbricated: membrane winged at the extremities; lower pointed: upper two-forked.

This also grows to a large tree, and is a native of the mountainous parts of the same coast. It flowers during the wet season, and the seeds are ripe about april.

The wood is exceedingly beautiful, its colour like that of the Box-tree but much lighter, and at the same time very close grained; it is to be had of a large size, from one to two feet or more in diameter; is used for almost every purpose where it can be kept dry, and answers very well for furniture, being pretty, light, and durable.

Daduga of the Telingas.

4. Trunk irregular, with a scabrous ash-coloured bark. Branches opposite, decussated. Leaves opposite, decussated, short-petioled, quite entire, very smooth and shining both above and below, from four to nine inches long. Stipules as in the two former. Peduncles as in *N. parvifolia.* Flowers larger than in either of the former, purple. Calyx as in *N. cordifolia.* Corolla, stamens, pistil and style as in the former. Stigma globular. Capsule turbinate, wants the outer covering, two-celled; the cells two-valved on the out

[a] Loureiro.

[b] Idem.

or convex fide; on the inſide there is only the receptacle of the fruit, which is broad. Seeds numerous, moſt minute, imbricated, with their inſertions upwards.

It is a ſmall tree: a native of the moiſt valleys among the Circar mountains, flowering in april or the beginning of the hot ſeaſon.—Bagada of the Telingas[a].

SPECIES.

1. Nectris aquatica.

Lin. ſyſt. ed. Gmel. 580.

Cabomba aquatica. *Aubl. guian.* 321. *t.* 124.

DESCRIPTION, *&c.*

This plant grows in ponds, lakes, and rivers that have not a rapid current, puſhing out long, branched, knotted, ſiſtulous ſtems, with a pair of leaves at each joint. Theſe leaves are divided into five branches, and each of theſe into three others, and ſo on three times, finiſhing by two; theſe diviſions are very fine: the top leaves float on the water; theſe are alternate, entire, oval, peltate, on a long petiole, like thoſe of Hydrocotyle. The flowers come out from the axils of theſe on a long peduncle: ſometimes there is a flower from the axil of one of the upper cut leaves. The three outer leaves of the calyx are green on the outſide, and yellow within; the three inner are entirely yellow.—Native of Guiana and the iſland of Cayenne[a].

DESCRIPTION, *&c.*

This elegant plant riſes with a fungoſe, thick, round ſtalk. Leaves alternate, ſeſſile, wide, oblong, ſmooth, with a very ſtrong nerve running along the middle, ending in a long tendril, generally twiſted, to which hangs a receptacle, or long, cylindrical, membranaceous, ſmooth, hollow bag, which on being preſſed yields a ſweet, limpid, pleaſant, refreſhing liquor, in ſuch quantity that ſix or eight of them are ſufficient to ſlake the thirſt of a man.

Flowers in a ſpike on long peduncles[a]. Calyx inferior, permanent; leaflets ovate, acuminate. Anthers four, fixed to the germ. Capſule ſuperior, oblong, ſwelling in the middle, narrowed to both ends, crowned with a depreſſed quadrangular diſk formed of the four ſeſſile ſtigmas, four-cornered, four-valved: the valves have a depreſſed line on the outſide, and a longitudinal ſeptum within. Seeds very numerous linear-oblong, narrowed to both ends, dirty ſtraw-colour, faſtened all round in a ſuberect poſition to the partition[a].

Native of the iſland of Ceylon. Linneus placed it in the claſs Gynandria; he doubted however about the ſex, and thought it might be dioecous, as it proves to be.]

[a] Roxb. coron. [a] See Wither. arr. ed. 3. p. 789. 790. 852.
* Aublet. [a] Linn. zeyl. & Burm. zeyl. [a] Gærtner.

NEPETA (*of Pliny: from* Nepa, *being ſuppoſed to be efficacious againſt the bite of the ſcorpion. Linnæus derives it from the name of a town in Italy, between Rome and Viterbo.*)

Lin. gen. n. 710. *Reich. n.* 768. *Schreb. n.* 964. *Juſſ.* 113. Cataria. *Tournef. t.* 95.

Claſs. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ. Labiatæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, cylindric: *mouth* five-toothed, acute, erect: *upper* toothlets longer; *lower* more ſpreading.

COR. one-petalled, ringent: *tube* cylindric, curved inwards: *border* gaping: *opening* ſpreading, cordate, ending in two reflex blunt very ſhort ſegments: *upper lip* erect, roundiſh, emarginate; *lower* roundiſh, concave, larger, entire, crenulate.

STAM. *Filaments* four, awl-ſhaped, beneath the upper lip, approximating, two of them ſhorter. *Authers* incumbent.

PIST. *Germ* four-cleft. *Style* filiform, length and ſituation of the ſtamens. *Stigma* bifid, acute.

PER. none. *Calyx* ſtraight, containing the ſeeds in its boſom.

SEEDS four, ſubovate.

OBS. *If the ſegments of the throat be numbered with the lower lip, it will be three-parted.*

ESSENTIAL CHARACTER.

Cor. lower lip with an intermediate ſegment, crenate; throat reflex at the edge. *Stam.* approximating.

SPECIES.

Betonica ſibirienſis. *Wolfb. hort.* 122. *n.* 20.
Flowers in ſpikes, leaves pinnatifid quite entire.

19. Nepeta botryoides.
Ait. hort. kew. 2. 287.
N. multifida. *Linn. ſuppl.* 273. *ſyſt.* 530. *Lamarck encycl.* 1. 713.

N. bipinnata.

N. bipinnata. *Carian. bisp.* 36. *n.* 55. *t.* 29.
Flowers in spikes, lateral lobes of the corolla somewhat spreading, leaves pinnatifid, segments linear almost equal.

20. Nepeta lavandulacea.
Lan. fisp. 530. *suppl.* 272.
Spike compact, leaves ovate gash-serrate marked with lines.]

DESCRIPTIONS, &c.

1. Common Nep or Catmint has a perennial root, from which arise many branching ſtalks, two feet high, [and more,] upright, pubeſcent. Leaves of a velvet-like ſoftneſs, wrinkled, aſh-coloured or hoary particularly underneath. Spikes compoſed of interrupted whorls terminate the ſtem, and come out in branches from the axils of the leaves. The flowers are ſubſeſſile, and ſeparated at the baſe by a ſmall lanceolate bractæ. Calyx downy with green ribs. Corolla white, with a tinge of red, and ſpotted with purple: tube nearly ſtraight; middle ſegment of the lower lip with ſix or ſeven (ſometimes more) equal teeth turned upwards, and ſet with a tuft of white briſtles at the baſe. Stamens rather longer than the upper lip. Seeds ovate three-ſided, blunt at both ends, crowned with a white ſtreak, dark brown and ſmooth when ripe [a]. The whole plant has a ſtrong ſcent between Mint and Pennyroyal. It is called Catmint, becauſe cats are very fond of it, eſpecially when it is withered, when they will roll themſelves on it, tear it to pieces, and chew it with great pleaſure. Ray obſerves, that plants which he tranſplanted from the fields into his garden were always deſtroyed by the cats, unleſs he proteſted them with thorns till they had taken good root and came into flower; but that they never meddled with plants raiſed from ſeed. Hence the old ſaying:

"If you ſet it,
"The cats will eat it;
"If you ſow it,
"The cats don't know it."

Mr. Miller has confirmed this by his own experience; having frequently ſet a plant from another part of the garden, within two feet of others which came up from ſeeds, when the former was torn in pieces and deſtroyed by the cats whilſt the latter remained unhurt. [The true reaſon of this difference is aſſigned by Ray: that the cat is fond of it in a languid withering ſtate, or when the peculiar ſcent of the plant is excited by being handled or bruiſed in gathering or tranſplanting.

Common Catmint is a native of moſt parts of Europe, on banks and hedges, chiefly in a calcareous ſoil. It flowers from july to ſeptember.

In German it is called *Nepte, Katzenneepte*, &c. In Dutch, *Kattekruid* or *Nept*. In Daniſh, *Katteurt* or *Siſeubrandt*. In Sweditſh, *Kattmynta*. In French, *Chataire, Cataire, herbe aux Chats*. In Italian, *Gattaria*. In Spaniſh, *Gatera*. In Portugueze *Neveda dos gates*. In Ruſſian, *Koſchitza michta*.

An infuſion of Catmint is deemed a ſpecific in chlorotic caſes. Two ounces of the expreſſed juice may be given for a doſe. Sheep are ſaid to eat it, but all other domeſtic quadrupeds to refuſe it[b]. Sheep might have been included in the number.]

β. The ſmaller Catmint, which Miller makes a diſtinct ſpecies, grows naturally in Italy and the South of France. The ſtalks are more ſlender, and their joints farther aſunder; the leaves are narrower, and the whole plant whiter: the ſpikes of flowers are divided into whorls, the lower two inches apart, others an inch, and the upper ones half an inch.

[2. Stem erect, a foot high, branched: the whole plant tomentoſe-hoary. Leaves petioled, blunt-iſh, half an inch long. Flowers corymbed. Corymbs pedicelled, oppoſite, cluſtered in a terminating, oblong, compact ſpike. Bractes ſtrait, linear. Calyx ſtriated, with lanceolate, acute teeth. It is by no means a variety of N. Cataria, nor does it change its appearance when cultivated in a garden. The leaves are ſharp at the baſe, all blunt at the tip: the calyxes are acute: whereas the leaves of N. Cataria are ſubcordate at the baſe; and the upper ones, as alſo the teeth of the calyx, are cuſpidate. N. anguſtifolia minor hiſpanica, *Barrel. ic.* 735. & *Boc. muſ.* 2. 75. *t.* 61. probably appertains to this, but the flowers are fewer and more remote in the figure.—Native of Arragon [c].]

Miller has a ſpecies under the ſame name, the ſtalks of which do not branch ſo much as the common ſort; they are ſlenderer and the joints farther aſunder; the leaves are ſmall, narrow, and almoſt heart-ſhaped, ſerrate, hoary, and on ſhort foot-ſtalks: the ſpikes of flowers are more broken or interrupted, and the whorls ſtand upon foot-ſtalks. It grows naturally in Italy.

He has another ſpecies which he calls N. paniculata, which grows naturally in Sicily, and riſes with a ſtrong ſtalk near three feet high, the lower joints are four or five inches aſunder. Leaves long, narrow, heart-ſhaped, deeply ſerrate, ſitting pretty cloſe to the ſtalk. Flowers in panicles, of a pale purpliſh colour.

[3. Root perennial, branched, woody, the ſize of a quill or more, brown on the outſide, knobbed at the end. Stems ſeveral, from three to four feet in height, grooved, ſmoothiſh, with oppoſite branches forming a panicle. Leaves oblong, blunt, ſcarcely cordate, bluntly ſerrate, ſmooth, the lower ones on longer petioles, the upper ones on very ſhort ones; they are ſucceſſively ſmaller as they approach the racemes, till they become ſo ſmall that the ends of the racemes ſeem to be leafleſs. Racemes axillary and oppoſite containing about twenty flowers. Bractes almoſt briſtle-ſhaped. Calyx ſomewhat villoſe and ſtriated. Corolla more or leſs red, in the cultivated plant very deep, and elegantly dotted: upper lip blunt, erect and bifid, with oblong flat ſegments; lower lip hairy on both ſides, with blue dots at the throat. Calyx of the fruit ovate. Seeds black. It is ſo nearly allied to N. nuda, as ſcarcely to be diſtinguiſhed when they are not in flower. The branches are not ſo rod-like in the nuda; the corollas in that are almoſt white, without ſpots, but the principal difference is in the lower lip, the middle ſegment of which in the nuda is flat with the ſides reverſed, but in this remarkably concave and hagging [d].

Native of Hungary, Auſtria, and Siberia. Cultivated in 1683, by Mr. James Sutherland. It flowers from auguſt to october.

4. Introduced in 1777, by Caſimir Gomez Ortega, M. D. We do not know of what country it is a native. It flowers in may and june [e].]

5. Stalks about two feet high, with a few ſlender branches coming out from the ſides. Leaves indented on their edges. Flowers in roundiſh whorls, pedunculed, blue. There is a variety of it with white flowers.

[According to Scopoli, the ſtem is the height of a man, ſmooth, glaucous at the angles. Racemelets axillary, twice and thrice dichotomous, with a naked flower interpoſed between each diviſion. Calyx rough-haired, ten-ſtreaked, ſubbilabiate. Helmet or upper lip of the corolla bifid, the ſegments rounded: lower lip dotted, pale: tube wider behind and ſerruginous. Filaments ſmooth. Fruiting calyx ovate, with converging, amethyſtine teeth. Seeds brown, convex on one ſide, angular on the other, appearing rough when examined by the microſcope, and having a white tranſverſe line at the baſe.

Native of Spain, Piedmont, Carniola, Siberia. It was cultivated in the botanic garden at Chelſea in 1723, and flowers from july to ſeptember [f].

6. Native of the Ukraine [g].

7. Stem herbaceous, roundiſh at bottom, decumbent, naked, bluntly four-cornered above, erect, tomentoſe, undivided, a ſpan or a little more in height. Leaves acute, tomentoſe on both ſides but whiter underneath, ſpreading, half an inch long, the upper ones gradually leſs. Petioles tomentoſe, a line in length. Panicles in the upper axils, oppoſite, trifid, ſaſtigiate. Peduncle a line in length: pedicels capillary. Stamens twice as long as the corolla. It differs from N. Nepetella in having the flowers in axillary panicles, and the leaves ovate-oblong, not cordate.—Native of Japan.

[a] Withering. Pollich. [b] Withering. [c] Vand. [d] Jacquin. [e] Hort. kew. [f] Idem. [g] Linn.

The Kew catalogue has a species under the same name, the native place of which is not known. It was introduced in 1778 by Mr. Thomas Blackie, and flowers in auguſt. The leaves are petioled oblong ſubcordate crenate tomentoſe; the flowers in cymes pedunculed and many together.

8. This is only one-third of the ſize of the common ſort. The leaves are very narrow, acutely ſinuate-toothed. Flowers looſely racemed, with about five flowers in the racemelets, and not thirty as in N. violacea. Calyxes naked. Bractes very narrow, ſpreading. Corollas, when recent, red, not white or blue. Anthers blue.

Native of the South of Europe [a]. Cultivated in 1758, by Mr. Miller. It flowers from july to ſeptember [b].

9. Stems two feet high, ſmooth, ſtrict, four-grooved, the older ones dark purple. Leaves like thoſe of Stachys paluſtris, blunt, veined, naked, rugged on both ſides. Racemes brachiate. Bractes linear. Flowers diſtinct. Corollas whitiſh-ruſeſcent, with the beard of the palate white, and the throat dotted with purple. According to Haller the flowers are blue and white [c].

Krocker deſcribes a plant under the name of *nuda*, but is doubtful whither he ſhould refer it, becauſe it has ſeveral characters of N. nuda, and ſeveral of ucranica, and that authors diſagree ſo much in their characters. He ſuſpects that theſe two may be one and the ſame plant, and is rather inclined to ſuppoſe that his may be the ucranica; the ſtem being four or five feet high; the leaves ſtrictly ſeſſile, rather lanceolate than cordate, bluntly ſerrate, not blunt at the end, but acuminate. Corolla pale blue, not white-ruſeſcent or dotted with red, but rather with white; and laſtly, the ſpikes being compoſed of rather long, oppoſite, many-flowered peduncles, placed in whorls, panicled, naked, without any bracte between them.

Native of the South of Europe. Cultivated by Mr. Miller in 1758. It flowers from june to auguſt [d].]

10. Stalks about two feet high, branching from the bottom. Leaves heart-ſhaped, obtuſe, little indented, on pretty long petioles. Stalks terminated by long ſpikes of flowers in whorls, ſeparate, ſeſſile, wrapped in a hoary down. Corolla white, appearing in july.—Native of Sicily.

[According to Loureiro, it is alſo a native of Cochinchina. He deſcribes the ſtem as one foot high, upright, hairy and pale. Leaves lanceolate, ſerrate, hirſute, ſeſſile. Flowers white, ſeſſile, in axillary whorls, with many hairs intermixed. Lower lip of the corolla wider, crenate, with the margin of the throat reflex. Stamens ſtraight approximating.]

11. The ſtalks of this ſeldom riſes more than a foot and half high, ſending out very few branches. The whorls of flowers which form the ſpike are diſtant from each other, and ſit cloſe to the ſtalk. Leaves ſhort, oval, heart-ſhaped. The plant is hoary and ſtrong ſcented.

[Leaves blunt, crenate. Bractes lanceolate, green except at the ſides where they are white, the length of the calyx, acuminate. Calyxes erect, equal. Corolla white.—Native of Italy [e]. Cultivated in 1739, by Mr. Miller. It flowers from june to auguſt [f].]

12. This has a thick knobbed root, from which come out one or two ſtalks, that often decline to the ground; they are about two feet and a half long, and ſend out two ſide branches oppoſite. Leaves oblong, crenate, ſeſſile, deep green. The upper part of the ſtalk, for more than a foot in length, has whorls of flowers, the lower ones two inches aſunder, but nearer all the way up: they ſit very cloſe to the ſtalks, and are guarded by ſmall bractes. The corolla is blue.

[Stems ſimple. Leaves cordate-oblong, wrinkled, bluntiſh, groſsly ſerrate, pubeſcent. Spike long, ſomewhat interrupted. Bractes numerous, erect, ovate, acute, nerved, coloured with red, pubeſcent at the edge, covering the calyxes. Flowers violet-coloured. There is a variety which is procumbent [g]; and that ſeems to be Mr. Miller's plant, for he ſays that it ſometimes has an erect ſtalk.

Native of Spain and Portugal. Cultivated in 1683, by Mr. James Sutherland. It flowers from june to auguſt [h].

13. Root large, from which proceed many tomentoſe leaves, like thoſe of White Horehound, ſpreading on the ground in a circle; from the middle of theſe riſe ſeveral ſtems, which are alſo very tomentoſe like White Horehound, and on the top of them are white flowers in a large thick ſpike. Seed black. The whole plant is larger and thicker than the common Scordium, for which they uſe it in Crete or Candia, where it grows abundantly on rocks, by way ſides, and on the borders of fields [i].

14. The root conſiſts of various fleſhy roundiſh or fuſiform tubers, the firſt year forming the root-leaves, and the ſecond many flowering-ſtems. Theſe are viſcid, ſet with long white villoſe hairs, in height one foot or eighteen inches, either entirely erect, or procumbent at the baſe. Leaves bluntiſh, crenate, wrinkled, viſcid, the lower petioled, the upper ſeſſile, all having a ſtrong ſmell. Spikes ſeſſile; the principal ones three or four inches long, thoſe on the branches ſcarcely an inch or an inch and half in length: they are compoſed of whorls, the lower ones ſometimes remote, the reſt cloſely approximated, hence reſembling a ſpike, and that the more, the nearer the upper leaves at the whorls approach to bractes: theſe are the length of the calyxes, purple at the edge, and are placed on a very ſhort common peduncle in the axil of the leaf. On each of theſe peduncles there are three, five, or ſeven flowers, each ſupported by its bracte. Calyxes ſtriated, hairy. Lips of the corolla ſlightly tinged with purple: throat pale dotted with purple and having a few villoſe hairs at the origin of the lower lip: the ſegments of the throat are not bent back: the upper lip is convex. Seeds brown, with a white hilum. The plant is more or leſs villoſe in different individuals and at different ages [k].

Its native place is not known. The ſeeds were ſent by Willich to Jacquin; and he introduced them at Kew in 1774. It flowers in may and june [l].]

15. Stems two feet high. Leaves hairy, ſomewhat like thoſe of Marjoram, but larger. Flowers in whorls, and terminating in a large roundiſh head. Stamens longer than the corolla, which is of a pale fleſh colour. [The lower lip of the corolla is ſerrate, but not concave [m].

Native of Virginia. Introduced 1788, by Thomas Walter, Eſq. It flowers in auguſt [n]. If N. virginica of Miller be the ſame, he cultivated it in 1759.

16. Stems erect, obtuſe-angled, tomentoſe. Leaves ovate-lanceolate, tomentoſe, ſerrate, quite entire towards the baſe, petioled. Whorls ſeveral, forming a ſort of interrupted ſpike, remote, with ſubform bractes, generally thicker at the tip, pubeſcent, two under each flower, the length of the calyxes. Calyx villoſe, five-toothed. Corolla pale violet: upper lip lanceolate, entire, concave with the edge rolled back, erect, blunt, ſhorter than the filaments: lower lip longer, wider, three-parted, the middle part larger, crenulate, bent down at the edge.—Native of Malabar: where it was found by Koenig [o].

17. The upper lip of the corolla is the ſhorteſt of all in this ſpecies, and entire. Stamens the length of the lower lip. Flowers in whorls. It is allied to the preceding, and a native of the Eaſt Indies. See Lavandula carnoſa.

18. Stem erect without branches. Lower leaves petioled, upper ſeſſile, not crenate, oblong, three-lobed, four-lobed or five-lobed; lobes alternate, oblong. Flowers very ſmall. Anthers two-parted.—Native of all Siberia beyond the river Jeniſea [p].

19. Stems ſeveral, erect, ſcarcely a foot high, decuſſately branched; branches oppoſite, erect. Leaves bipinnate; pinnules linear, blunt: petioles ſhorter, ſomewhat embracing, channelled. Spikes terminating,

[a] Linn. [b] Hort. kew. [c] Linn. mant. [d] Hort. kew. [e] Linn. [f] Hort. kew. [g] Bellon. obſ. Clus. [h] Jacqu. obſ. [i] Herb. kew. [k] Linn. [l] Hort. kew. [m] Linn. mant. [n] Linn. ſpec.

elongated, conical; in which are innumerable, minute, subsessile flowers, accompanied with bristle-shaped bractes, arched upwards. Calyx oblong, turbinate, striated; the two lower toothlets shorter than the upper ones. Corolla white, a little longer than the calyx: tube turbinate: border two-lipped; upper lip very short, scarcely emarginate, villose above; lower trifid, with the lateral segments blunt, not emarginate, the middle one hanging down, longer, two-lobed. Filaments short: anthers ovate, twin, concealed within the upper lip. Seeds oblong, ovate on the outside, flattish, somewhat keeled within and smooth.—Native of Siberia [1].

Cavanilles observed it in flower at Madrid. Introduced in 1779 by Messrs. Kennedy and Lee. It flowers in june and july [2].

20. Stem erect, brachiate, round, purple, with white hairs, a span or a foot in height. Leaves bluntish, deeply and bluntly serrate, like those of Veronica officinalis; the lower ones quite entire. Petioles almost the length of the leaves. Spike terminating, bluntish, ovate-oblong. Bractes close, ovate, acute, the length of the calyx. Flowers sessile. Calyx of a dusky blueish colour and hairy. Corolla violet-coloured, very large; upper lip acutely bifid, lower scarcely crenate. Two stamens the length of the upper lip, two beyond the throat. Anthers two-parted.—Native of Siberia [1].]

PROPAGATION AND CULTURE.

All these plants are hardy herbaceous perennials, except one or two that are biennials. If the seeds be permitted to fall, the plants will rise without trouble; or being sown either in spring or autumn, will come up, and require only to be thinned where they are too close, and kept clean from weeds. Upon a poor dry soil they will not grow too rank, but continue much longer and appear handsomer than in rich ground, where they grow too luxuriant, and have not so strong a scent.

Lin. syst. 851. *Reich.* 4. 136. *mant.* 125. *Gærtn. fruct.* 2. 272.

DESCRIPTION, *&c.*

Leaves alternate, pinnate, two-paired, abrupt: leaflets obovate, the outer ones larger. Raceme consisting of a few spikelets, erect, shorter than the leaves [3]. The fruit, according to Gærtner, consists of two capsules, one of which however is generally abortive, coriaceous, thick, ovate, turgidly lenticular, muricated on the outside with awl-shaped, flexile bristles, within ferobicular-rugged, one-celled, opening at the inner edge. Seeds solitary, large, ovate, very slightly compressed, somewhat bertied [4].

Jussieu ranges this plant with Ambrosia and Xanthium; but the inverted situation of the embryo alone, says Gærtner, is sufficient to forbid this union, even if they agreed in all other circumstances. He thinks that it approaches nearer to the Chestnut, because it it has two styles to each capsule, and no albumen.

Native of the East Indies.

DESCRIPTIONS, &c.

These are beautiful evergreen shrubs or trees, upright and branching. Leaves opposite, or by threes in a sort of whorl. Flowers in cluters or corymbs from the ends of the stem and branches.]

1. This rises with several stalks to the height of eight or ten feet. The branches come out by threes round the principal stalks, and have a smooth bark, which in that with red flowers is of a purplish colour, but in that with white flowers is of a light green. The leaves for the most part stand by threes round the stalks, upon very short foot-stalks, and point upwards; they are three or four inches long, and three quarters of an inch broad in the middle, of a dark green, very stiff, and end in acute points. The flowers come out at the end of the branches in large loose bunches, and are of a bright purple, or crimson colour, or of a dirty white. The seed-vessels are brown follicles, about four inches long. It flowers in july and august, and in warm seasons the flowers are succeeded by pods, but the seeds seldom ripen well in England.

In warm dry summers this plant makes a fine appearance, the flowers then opening in great plenty; but in cold moist seasons the flowers often decay without expanding, unless the plants are placed in a greenhouse or under a glass-case. That with white flowers is the most tender.

[Other varieties are the stripe-leaved; the broad-leaved double-flowered, the striped double-flowered, and different shades of red from purple to crimson or scarlet.

Jussieu remarks that Nerium Oleander is not milky.

Native of the Levant, Spain, Portugal, Italy, by the sides of streams, and near the sea coast. It abounds every where in the island of Candia or Crete by rivers and torrents, and there the variety with white flowers is chiefly found; in the mountains and plains about Antioch or Scanderoon it is found abundantly; in Sicily, by all the torrents descending from mount Etna; in many parts of Italy, as between Nice and Genoa, near mount Baldo, &c. but particularly in all the low grounds of Magna Graecia in the kingdom of Naples. Belon says that in Crete and on mount Athos the Rhododendron, which is this shrub, grows to a great size, insomuch that in Crete it is sometimes used for building timber. It has the name Rhododendron, from the similitude of its flowers in size and colour to a rose: Rhododaphne for the same reason, and because, as Gerarde expresses it, it makes a gallant shew, like the Bay-tree. Hence also our English name *Rose-Bay*; but it is now more commonly known by its officinal name, *Oleander*; which is also adopted into all the European languages, except the French, in which it is *Laurier* or *Laurier-Rose*, that is *Bay-Rose*. The Italians have adopted *Nerio* and *Rosalauro*, as well as *Oleandro*. It was cultivated by Gerarde in 1596.

The leaves of Oleander are acrid and poisonous, therefore certainly not proper to be used internally without great caution. Oil, in which the leaves are infused, is recommended in the itch and other cutaneous disorders, in preference to mercurial preparations, for children and delicate constitutions[a].]

2. This rises with shrubby stalks six or seven feet high, covered with a brown bark. Leaves stiff, from three to four inches long, and not more than a quarter of an inch broad, of a light green, and the edges reflexed; they are opposite, or alternate, or by threes round the branches. The flowers are produced in loose bunches at the end of the branches; they are of a pale red, and have an agreeable musky scent. It grows naturally in India.

[This has been confounded with the first species.— It was cultivated in 1758, by Mr. Miller, and flowers from june to august[b]. Probably the N. Oleander of Thunberg and Loureiro is this species. The latter however asserts that his plant has scarcely any smell.]

β. Leaves six inches long, and one inch broad in the middle, of a much thinner texture than those of the first, and their ends are generally reflexed; they are of a light green, and irregularly placed on the branches by pairs, alternately, or by threes. The flowers are produced in very large bunches at the end of the branches, upon long peduncles; they have three or four rows of petals one within another. They are much larger than those of the common sort, and smell like those of Hawthorn. The plain flowers are of a soft red or Peach colour; but in most they are beautifully variegated with a deeper red, and make a fine appearance. The usual time of flowering is in july and august, but in a warm stove it will continue in flower till michaelmas. The flowers being double, they are not succeeded by seeds.

All these are supposed to have a poisonous quality; the young branches, when cut or broken, have a milky juice or sap, and the larger branches, when burnt, emit a very disagreeable odour.

Mr. Miller says it grows naturally in both Indies, that it was first introduced into the British islands in America from the Spanish Main, and that it is called by the inhabitants of those islands South Sea Rose. The beauty and sweetness of the flowers engaged the inhabitants to cultivate the plants, and in many places to form hedges of them, but many of the cattle that browzed on them were killed, so that they are now only preserved in gardens, where they make a fine appearance great part of the year.

[N. odorum was cultivated by Mr. Miller in 1758[c].] He says that the double Indian Rosebay was not known here till the beginning of last century, [by which I suppose he intended the beginning of the present century. Dr. Patrick Browne says that the South Sea Rose is cultivated in most gardens in Jamaica; that it generally bears large double flowers, but that he has sometimes found them simple and fertile, with all the characters of the genus[c].

3. This is allied to N. Oleander, but differs in having the leaves blunt, somewhat veined underneath, but not with very abundant transverse nerves.

4. Trunk soft, resembling a bulb under ground, the size of a man's head. Branches the thickness of the little finger, the same substance with the trunk, attenuated above; when flowering woody and warted. Leaves at the ends of the branches, approximating, subpetioled,

[a] Allione. [b] Hort. kew. [c] Idem. [c] 181. 3.

subpetioled, often three inches long, mucronate, veinless; the younger ones soft on both sides. There are some rigid bristles in the axils of the leaves. Corymbs terminating, many-flowered. Flowers on short villose pedicels. Calyx scarcely two lines in length, pubescent, with lanceolate segments. Tube of the corolla narrowed at bottom for the space of two lines, then widening, an inch long, pubescent, with five villose longitudinal lines within: segments of the border rounded. Filaments in the narrower part of the tube. Anthers cohering with the stigma at top, yellow with a brown spot on the inside, ending at top in a hairy bristle the length of the corolla. Germs two, globular: style one, the length of the anthers: stigma capitate, two-toothed at top, five-toothed at the sides. Although the leaves are scattered, which is seldom the case in the Contortæ, yet the form of the anthers and their coalesion with the stigma prove it to be of this genus. By the corolla and naked throat it approaches to Echites, but the glands at the base of the germ are wanting; and since the anthers are tailed, it seems better to retain this plant among the Neriums, till we become acquainted with the fruit[1].

5. Stems round, very dark purple, smooth, erect, swelling at the joints. Leaves oblong, acuminate, resembling those of Myrtle, green on both sides. Flowers at the ends of the branches[2]. Germs two, superior, coadunate into a single style. Pericarp two coriaceous follicles, very finely striated on the outside, very smooth within, fusiform, one-celled, opening on the inner side. Seeds numerous, fusiform, somewhat wrinkled, ash-coloured, crinite. Hairs simple, white and silky, four times as long as the seed, fastened by the base on both sides to the sutures of the follicles, and hanging down so that the hairy vertex is turned towards the bottom of the pericarp[3].—Native of the East Indies.

6. Stem frutescent, round, decumbent or scandent, ferruginous. Branches alternate, divaricating, villose. Leaves opposite, ovate with a blunt point, quite entire with a reflex margin, parallel-nerved, paler underneath, smooth, an inch long, the last smaller. Petioles semicylindric, scarcely a line in length. Flowers in panicles at the ends of the branches. Panicle dichotomous and trichotomous. Peduncles and pedicels filiform, smooth. Calyx shorter than the tube of the corolla. Corolla white. Stigma capitate, truncate[4].

According to Loureiro it is a middle-sized tree; leaves waved, shining; flowers reddish yellow, with a reflex border, and the segments of the crown or nectary awl-shaped and short; anthers subsessile, sagittate, converging into a cone; style cylindric, thickish, sheathing another above it; stigma ovate; follicles round, long, almost united, erect.—Native of the East Indies, Japan, and Cochinchina.

7. This also is a middle-sized tree, with brachiate branches. Leaves opposite, flat, quite entire, smooth. Flowers herbaceous or greenish white, in short subterminating racemes. Segments of the crown oblong, alternately trifid and linear.

The wood of this and the preceding species is proper for the turner, and to make cabinets and other elegant furniture. It is very white and of a fine grain, like ivory, only much lighter. It mixes admirably with ebony. It is reputed to be a specific in the dysentery[5].

Native of the East Indies, Cochinchina, and some parts of the Russian empire.—Introduced in 1778, by Patrick Russell, M. D.[6]

Nerium tinctorium is a middle-sized tree, from the quality of its leaves called Nerium tinctorium, or Dyer's Rose-Bay, by Dr. Roxburgh. It comes nearest Nerium antidysentericum, the tree which yields the Coneesi bark, of our Materia Medica; Codago Pala of the Hortus Malabaricus, Pala Cadija of the Hindoos; they are both natives of the lower region of those mountains, which bound the Rajahmundry Circar on the north side, and are so much alike in most respects, the nectary excepted, that, without a perfect knowledge of both, the one may be mistaken for the other; and I have no doubt but the bark of this new Nerium might have been gathered and sold for Coneesi bark; which with the Hindoos is esteemed a specific in most complaints of the bowels, and perhaps deserves a better name, than it has hitherto acquired in Europe.

Description of Nerium tinctorium.—Trunk, very irregular in shape, when very old it is from one and a half to two feet in diameter, but when of that size, it is full of large rotten cavities; its height to the branches, when large, is from ten to fifteen feet; the bark of the old wood is scabrous, of the young pretty smooth and ash-coloured. Wood remarkably white, close-grained, very beautiful, coming near to Ivory in appearance. Branches irregularly disposed, being bent in various forms: branchlets opposite. Leaves numerous, opposite, on short foot-stalks, oval, pointed, pretty smooth, entire, pale green, when full grown from five to eight inches long, and from three to four broad. Flowers about an inch and half in diameter when expanded, perfectly white, fragrant, and disposed on lax globular panicles, at the extremity of the branches. A small oval bracte below each subdivision of the panicles. Calyx below the germ, divided into five equal, semiorbicular segments. Segments of the corolla linear, oblong, spreading. Nectary consists of many ramous white filaments crowning the mouth of the tube. Anthers rigid, united to one another laterally, forming a very firm conical cover for the stigma, their lower parts are covered with fine white hairs. Germs two, seemingly united. Stigma double, covered with transparent gluten, by which it adheres to the inside of the anthers. Pericarp two very long slender pendulous follicles, united at both ends; singly they are from twelve to twenty inches long, and about as thick as a common pencil.

This tree, as observed before, is a native of the lower regions of the mountains directly north from Coringa, in the Rajahmundry Circar; it contains a mild milky juice, chiefly the tender branches and young leaves, which flows out on being wounded.—Nerium antidysentericum contains a similar juice.

The natives make scarcely any use of this tree, except for fire-wood, and the more it is cut down, the more it increases, many shoots issuing from the old stumps. These, in one year, acquire the height of eight or ten feet, and are thick in proportion; it casts its leaves during the cold season, (perhaps it may not do so in a state of cultivation.) About the beginning of the hot season, march and april, the young leaves begin to make their appearance, together with the flowers, by the end of may, those that first began to be unfolded will have attained to their full size; about this time also it ceases flowering, and the seed vessels are fully formed, but the seeds are not ripe till january or february.

The colour the leaves sometimes acquired, in drying for the Hortus Siccus, first induced Dr. Roxburgh to think they were possessed of colouring matter, and the result of some experiments fully answered his expectations, although he has been often deceived by the same appearances in the leaves of other plants.

The method he took to extract the colour was, by collecting, promiscuously, the large and small leaves, while fresh; putting them on the fire in common unglazed earthen pots, with soft well water, and, when scalding hot, straining off the liquor, which had acquired a deep green colour, with something of the violet coloured scum that is observed on the common Indigo, not towards the end of the fermentation: with little agitation, this liquor began to granulate; to promote the granulation as well as the precipitation, he tried various liquors; viz. cold infusion of Jamblong bark (Jambolifera pedunculata of Linneus) which is that the Hindoos use universally on this part of the coast, to precipitate their Indigo; lime water; a lixivium of wood-ashes; a mixture of lime-water and lixivium of wood-ashes, and also a ley, made of equal parts of caustic vegetable alkali and quick-lime; these five he repeatedly tried, and as often found that lime-water and a lixivium of wood-ashes mixed together answered best; the fæcula was washed, filtrated and dried in the usual manner.

[1] Vahl. [2] Burm. zeyl. [3] Gærtner. [4] Thunberg. [5] Loureiro. [6] Hort. kew.

The quick and luxuriant growth of this tree, in its native *soil*, will be a great inducement to those who wish to cultivate it; which can require little or no trouble, and the soil that it is always found wild in, is the barren dry rocky hills, and lower region of mountains, which is totally unfit for every sort of agriculture. The lower parts of the steepy rocky mountains of Saint Helena, seem to be the very soil and situation it delights in; its size and quick growth will render it valuable there, if it be only for fire-wood; with that view Dr. Roxburgh sent a pretty large quantity of seeds to the Planter's Society on that island.

It may be said that we are already in possession of a sufficient number of good blues, consequently that it is unnecessary to attend to this new Indigo; to obviate this objection, it may be observed, that the common Indigo plant is only to be brought to perfection by nice, expensive, and labouring culture; is liable to many accidents, from changes of weather, and other causes that no human foresight can prevent: these are well known facts to every one that cultivates Indigo to any extent. This tree is not subject to these inconveniences; besides it requires not the smallest care, is found in the greatest abundance, growing wild in the most barren tracts that can possibly be imagined, and requires only to be cut down once every year, to make it produce a large supply of young shoots with very luxuriant leaves the following season; besides, the colour that this Indigo may give to cloth, &c. may be different from any other hitherto known, consequently, may prove of considerable benefit to a commercial nation like Great Britain.

Dr. Roxburgh's experiments do not yet enable him to determine, with precision, the proportion of pure colouring-matter these leaves yield, but he has reason to think it will be about one in two hundred, that is two hundred pounds of the fresh leaves, produce one pound of Indigo, which is rather more than the leaves of the common Indigo plant yield †.

8. This is an elegant branched shrub, four feet high, milky, with an ash-coloured bark. The younger branches are shining, green, compressed a little, opposite at the end. Leaves long, lanceolate, acute, quite entire, shining, on short petioles, opposite. Peduncles one-flowered, thickish, in pairs from the divisions of the branchlets and decussating with them. Flowers handsome but without scent; perianth green; tube of the corolla greenish yellow; border snow-white. It approaches to Gardenia, but seems rather to belong to this genus *.—Native of the East Indies. Cultivated in 1770 by Mr. James Gordon. It flowers most part of the summer *.

9. This is a large shrub with feandent branches. Leaves ovate-oblong, quite entire, subacuminate, smooth, opposite. Flowers large, with a white tube and a very red border. Calyx five-cornered, with fleshy, upright segments. Tube of the corolla cylindric at bottom, pitcher-shaped at top; segments of the border, subulate-linear, very long, reband. Nectary as in the other species. Anthers ending in a very long filiform tail. Germ superior, two-lobed. Style the length of the stamens. Stigmas two one over the other; the lower cylindric, the upper acute, parted, erect. Follicles horizontal, thick, blunt. Although the very long segments of the corolla cause this to be allied to Echites caudata, yet the throat having a nectary, whereas in Echites it is naked, and the Contortæ being best distinguished by their nectaries, it ranges most properly under this genus. The follicles being horizontal is no obstacle, when other circumstances agree.—Native of Cochinchina *.]

PROPAGATION AND CULTURE.

These plants are generally propagated by layers in this country, for although they will sometimes take root from cuttings, yet that being an uncertain method, the other is generally pursued; and as the plants are very apt to produce suckers, or shoots from their roots, those are best adapted for laying, for the old branches will not put out roots; when these are laid down, they should be slit at a joint, in the same manner as is practised in laying Carnations, which will greatly facilitate their taking root: if these branches are laid down in autumn, and are properly supplied with water, they will have taken root by that time twelvemonth, when they should be carefully raised up with a trowel; and if they have taken good root, they should be cut off from the old plant, and each planted in a separate small pot, filled with soft loamy earth; those of the common sort will require no other care, but to be placed in a shady situation, and gently watered as the season may require, till they have taken new root; but the two other species should be plunged into a very moderate hot-bed, to forward their taking root, observing to shade them from the sun in the heat of the day; after the common sort has taken new root, the plants may be placed in a sheltered situation with other hardy exotics, where they may remain till the end of october, when they should either be removed into the green-house, or placed under a hot-bed frame, where they may be protected from frost in winter, but enjoy the free air at all times when the weather is mild.

This sort is so hardy as to live abroad in mild winters, if planted in a warm situation; but as they are liable to be destroyed in severe frost, the best way is to keep the plants in pots, or if they are very large in tubs, that they be sheltered in winter, and in the summer removed abroad, placing them in a warm sheltered situation. In the winter they may be placed with Myrtles, and other of the hardier kinds of exotic plants, in a place where they may have as much free air as possible in mild weather, but screened from severe frost; for if these are kept too warm in winter, they will not flower strong, and when the air is excluded from them, the ends of their shoots will become mouldy; so that the hardier they are treated, provided they are not exposed to hard frosts, the better they will thrive.

The other two sorts require a different treatment, otherwise they will not make any appearance; therefore the young plants when they have taken new root, should be gradually inured to bear the open air, into which they should be removed in july, where they may remain till october, provided the weather continues mild; but during this time, they should be placed in a sheltered situation; and upon the first approach of frost, they should be removed into shelter, for if their leaves are injured by frost, they will change to a pale yellow, and will not recover their usual colour till the following autumn. These sorts may be preserved in a good green-house through the winter, and the plants will be stronger than those which are more tenderly treated; but in may, when the flower-buds begin to appear, the plants should be placed in an open glass-case, where they may be defended from the inclemency of the weather; but when it is warm weather, the air should at all times be admitted to them in plenty. With this management the flowers will expand, and continue long in beauty; and during that time, there are few plants which are equal to them, either to the eye or nose, for their scent is very like that of the flowers of the White Thorn; and the bunches of flowers will be very large, if the plants are strong.

DESCRIPTION, *&c.*

Root fibrous, annual. Stems herbaceous, procumbent, rooting at the joints, branched, leafy, filiform, somewhat angular, smooth. Branchlets axillary, opposite, erect, one-flowered, short. Leaves opposite, petioled, orbiculate-cordate, bluntish, quite entire, even; stem-leaves spreading, branch-leaves erect-appressed. Petioles roundish, grooved above, almost the length of the leaves. Flowers solitary at the ends of the branchlets, sessile, pale. Bractes two, opposite, acute, very small. Berry succulent, very smooth, red, the size of a pea.

Found by Mutis very frequently in wet marshy places of New Granada[5]. It is also a native of New Zealand[6].

1. Neurada procumbens.
Lin. spec. 631. *fil.* 438. *Reich.* 2. 406. *hort. upf.* 117. *Forst. defer.* 90.

DESCRIPTION, *&c.*

This is an annual plant: the whole herb is white, with a nap like that of a cobweb. Cotyledons sagittate. Stems depressed, rigid, round, a palm high or more. Branches from each of the lower axils. Leaves alternate, petioled, ovate, plaited, sinuated as if gnawn, above less white or tomentose. Flowers axillary, subsessile[4]. The stem seems shrubby. Stem not five-cleft but manifoldly imbricate.—Native of Egypt, Arabia, and Numidia[3].

Class. 10. 1. Decandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate, thick, coloured, four-parted: *segments* wide concave, blunt; the two opposite outer ones larger, and the two internal ones less.

COR. one-petalled: *tube* very short: *border* deeply ten-cleft: *segments* oblong, imbricate, curved inwards at top, rigid.

Nellary, a short membranaceous ring, surrounding the base of the germ.

STAM. *Filaments* ten, very short, connected with the nectary, inserted into the receptacle. *Authers* linear, four-cornered, acute, erect, approximating.

PIST. *Germ* ovate. *Style* short. *Stigma* peltate, orbicular, six-rayed.

PER. *Berry* roundish, six-grooved, three-celled.

SEEDS very many, very small, angular.

ESSENTIAL CHARACTER.

Cal. turbinate, coloured, four-parted. *Cor.* one-petalled, ten-cleft. *Germ* encircled with a membranaceous ring. *Stigma* peltate, orbicular, six-rayed. *Berry* roundish, six-grooved, three-celled, many-seeded.

SPECIES.

Nicandra amara.
Lin. fil. ed. Gmel. 677.

Potalia amara. *Amb. guian.* 394. *t.* 151.

DESCRIPTION, *&c.*

Stem simple, straight, hard, woody, knotty, the thickness of a finger. Leaves simple, entire, smooth, narrow at the base, wide above, rounded, and pointed at the end, a foot and half long, and five inches wide, with a protuberant midrib underneath; they are opposite and decussated: petiole rounded, attached to a sheath that embraces the stem. Flowers terminating, on one, two or three peduncles, the base enveloped in a sheath. Each peduncle bears two or three little parcels of three, four or five opposite flowers, having also a little sheath at their base: each flower has its pedicel, with two scales at its origin. The calyx is of a golden colour. The corolla is white. The fruit is yellow, fleshy, the size of a cherry.

Native of Guiana, in the extensive forests; flowering in july and august, and fruiting in october. All parts of the plant are bitter: the leaves and tender twigs are used in venereal cases, and where there is suspicion of poison: in a large dose it is highly emetic *.

NICKER TREE. See *Guilandina.*]

NICOTIANA. (*This genus takes its name from Jean Nicot of Nismes in Languedoc, agent from the king of France to Portugal, who procured the seeds from a Dutchman, who had brought them from Florida, and sent them to France.*)

DESCRIPTIONS, *&c.*

[Theſe are herbaceous annual plants, except the firſt, which is fuffrutefcent or has a permanent baſe. Flowers in ſpikes or panicles at the ends of the ſtem and branches. Leaves quite entire, except in *urens*, the capſule of which opens in the ſame manner with that of Acanthus, whence Juſſieu conjectures that it may be of a different genus.]

1. This riſes with very branching ſtalks about five feet high. Lower leaves a foot and half long, broad at the baſe, where they half embrace the ſtalks, and about three inches broad in the middle, terminating in long acute points. The ſtalks divide into many ſmaller branches, terminated by looſe bunches of flowers of a bright purple colour, ſucceeded by acute-pointed ſeed-veſſels. The ſeeds were ſent to Mr. Miller for Brazil Tobacco.

[Linnæus obſerves, that it reſembles N. Tabacum ſo much, as to give room to ſuppoſe, that it is ſcarcely any thing more than a variety of it, with a permanent baſe. He ſets it down as a native of the Cape of Good Hope and of China. It is probably not indigenous of the former. In the latter and in Cochinchina it is cultivated every where; according to Loureiro, it has its proper vernacular names, and is regarded as indigenous.—It was cultivated here in 1699, by the Dutcheſs of Beaufort, according to the Kew catalogue. Sir George Staunton informs us that great quantities of Tobacco are planted in the low grounds of China, through which the embaſſy paſſed; and that there is no traditional account of its being introduced into that country, or into India, where it is likewiſe cultivated and uſed in vaſt abundance. In neither country are foreign uſages ſuddenly adopted. It is poſſible, that like the Gin-ſeng, it may be naturally found in particular ſpots, both in the old and new world[1].

Nieuhoff (in 1662) ſays, that the weed called *Tobako* by the Malayans and Javaneſe after the Portugueſe, grows in all parts of the Indies. We are not told whether the plant cultivated in the eaſt is ſhrubby or herbaceous; but Nieuhoff informs us, that about Batavia it grows to the height of eight feet, with leaves of eighteen inches long and eight broad: and Loureiro deſcribes the ſtem as four feet high, ſomewhat ſhrubby, thick, round, white, hairy, upright, branched. Leaves broad-lanceolate, quite entire, waved, wrinkled, ſoft, juicy, ſubſeſſile, half-embracing, alternate. Flowers whitiſh red, on upright, terminating racemes. Border of the corolla ſpreading, with the ſegments acute.]

β. This riſes about five feet high. The ſtalk does not branch ſo much as that of the former. The leaves are large and oval, about fifteen inches long and two broad in the middle, but diminiſh gradually in ſize to the top of the ſtalk, and with their baſe half embrace it. The flowers grow in cloſer bunches than thoſe of the former, and are white. They are ſucceeded by ſhort, oval, obtuſe ſeed-veſſels. It flowers and perfects ſeeds about the ſame time with the former. It grows naturally in the woods of the iſland of Tobago, whence the ſeeds were ſent to Mr. Philip Miller by Mr. Robert Millar.

2. [Virginian Tobacco has a large, long, annual root; an upright, ſtrong, round, hairy ſtalk, branching towards the top; leaves numerous, large, pointed, entire, veined, viſcid, pale green; bractes long, linear, pointed; flowers in looſe cluſters or panicles; calyx hairy, about half the length of the corolla, cut into five narrow ſegments; tube of the corolla hairy, gradually ſwelling towards the border, where it divides into five folding acute ſegments of a reddiſh colour[2]. Capſule ovate-conical, clothed with the calyx, ſmooth, with four depreſſed ſtreaks, two-celled, opening four ways at top; partition ſimple, contrary to the valves. Receptacle very large, fungous, ovate-acuminate, convex on one ſide, and flat on the other, or ſeuiform-concave, faſtened on both ſides to the partition. Seeds

[1] Embaſſy, 2. 154. [2] Woodville.

very numerous, ſmall, ovate, ſubreniform, with raiſed lines or nerves beautifully netted, of a yellowiſh bay colour[a].]

Mr. Miller has made three ſpecies of the Virginian Tobacco.

α. The great broad-leaved, which he ſays was formerly the moſt commonly ſown in England, and has been generally taken for the common broad-leaved Tobacco of Caſpar Bauhin and others, but is very different from it. The leaves are more than a foot and half long, and a foot broad, their ſurfaces very rough and glutinous, and their bales half embrace the ſtalk. In a rich moiſt ſoil the ſtalks are more than ten feet high, and the upper part divides into ſmaller branches, which are terminated by looſe bunches of flowers, ſtanding erect: they have pretty long tubes, and are of a pale purpliſh colour. It flowers in July and auguſt, and the ſeeds ripen in the autumn. This is the ſort which is commonly brought to market in pots, and by ſome is called Oroonoko Tobacco.

β. The ſtalks of this, which is the broad-leaved Tobacco of Caſpar Bauhin, ſeldom riſe more than five or ſix feet high, and divide into more branches. The leaves are about ten inches long, and three and a half broad, ſmooth, acute, ſeſſile; the flowers are rather larger, and of a brighter purple colour. It flowers and perfects ſeeds at the ſame time; and is called by ſome ſweet-ſcented Tobacco.

γ. Narrow-leaved Virginian Tobacco, riſes with an upright branching ſtalk, four or five feet high. The lower leaves are a foot long, and three or four inches broad: thoſe on the ſtalks are much narrower, leſſening to the top, and end in very acute points, ſitting cloſe to the ſtalks; they are very glutinous. The flowers grow in looſe bunches at the top of the ſtalks; they have long tubes, and are of a bright purple or red colour. They appear at the ſame time with the former, and their ſeeds ripen in the autumn.

Theſe are all natives of America. [Tobacco was cultivated in England before 1570, as appears from Lobel[t]. According to Linnæus it was known in Europe from 1560. Hernandez de Toledo is ſaid to have ſent it into Spain and Portugal, when Nicot being reſident in the latter from the moſt Chriſtian King Francis II. ſent it to Catherine de Medicis, as a plant of the new world, poſſeſſing extraordinary virtues. Geſner, in his Epiſtolæ medicinales, fol. 79. dated nov. 5. 1565, relates ſome trials which he made on it; and adds—"a Gallis Nicotianam vocari audio, nomine "legati cujuſdam qui Galliæ intulerit, ab aliis Pon-"tianam." He had then only learnt from Thevet that it was uſed in America for ſmoking.

Sir William Baker, in his Chronicle, (p. 400, ed. 9. 1696.) affirms that Tobacco was firſt brought into England from the Weſt Indies by Ralph Lane, in the 18th year of Queen Elizabeth, 1586. But this account muſt be underſtood of ſmoking the herb, or elſe it is inconſiſtent with the cultivation of it in 1570, as related by Lobel.

Hakluyt, in his Remembrances made in the year 1582, ſays, that "the ſeed of Tobacco hath been "brought hither out of the Weſt Indies, that it grow-"eth here, and with the herb many have been eaſed "of the rewmes, &c."

Tobacco it is well known is of a narcotic quality, which it generally diſcovers, even in ſmall quantity, when firſt applied. Even a ſmall quantity, ſnuffed up the noſe, will ſometimes produce giddineſs, ſtupor and vomiting; and when applied in different ways, in larger quantity, there are many inſtances of its more violent effects, even of its proving a mortal poiſon. In all theſe inſtances it operates in the manner of other narcotics: but along with its narcotic qualities it poſſeſſes alſo a ſtrongly ſtimulant power, perhaps with reſpect to the whole ſyſtem, but eſpecially with reſpect to the ſtomach and inteſtines, ſo as readily, even in no great doſes, to prove emetic and purgative.

The practices of taking Tobacco in ſnuff, by ſmoking and chewing, have now been common in Europe above two hundred years. Like other narcotics, the uſe of it may be introduced by degrees, ſo that its peculiar effects, even from large quantities, may ſcarcely appear: it has however its limits, ſo that in perſons who have been long in the habit of taking it, going only a little beyond the doſe to which they have been accuſtomed, very violent effects are ſometimes produced.

The effects of the different modes of thus uſing Tobacco depend chiefly upon its narcotic power, and certain circumſtances accidentally attending its application to the noſe and mouth. But on account of its ſtimulating quality, it is ſometimes employed, chiefly by the vulgar, to excite vomiting, but more commonly as a purgative in glyſters, or by throwing the ſmoke up the anus.

Externally an infuſion of Tobacco leaves has been uſed with advantage as a lotion for obſtinate ulcers; but many inſtances of its having been abſorbed and proving a violent poiſon, diſſuade from ſuch a practice, eſpecially as there are other medicines of as much efficacy, that may be employed with much more ſafety. Bergius recommends it for a fomentation in the paralyſmoſis. The ſmoke has been ſucceſsfully uſed in the way of injection, for obſtructions and inveterate conſtipations of the belly, ever ſince the time of Sydenham, and is alſo recommended in caſes of ſuſpended animation.

Reſpecting its poiſonous effects, in Ephem. nat. cur. (*dec. 2. ann.* 10. *obſ.* 131. *p.* 222.) we are told, that by the immoderate uſe of ſnuff, ſomnolency, and at length fatal apoplexy, was induced. Hellwig gives two inſtances of the ſame kind, occaſioned by ſmoking ſeventeen or eighteen pipes of Tobacco. Its effects by abſorption from external uſe may be ſeen in the ſame Ephemerides (*ann. 4. p. 46. & ann. 2. obſ. 108. p. 262.*) and in Alſton's Materia Medica. The oil of Tobacco applied to a wound, is ſaid by Redi to be as fatal as the poiſon of a viper. Albinus however did not find that this was the caſe with the animals on which he tried the experiment. This oil, given to pigeons, produced fatal effects, and was conſtantly attended with vomiting[u].]

3. The ſtalks of this ſeldom riſe more than three feet high. Leaves ſmooth, alternate, upon ſhort foot-ſtalks. Flowers in ſmall looſe bunches on the top of the ſtalks, of an herbaceous yellow colour, appearing in july, and ſucceeded by roundiſh capſules, ripening in the autumn.

This is commonly called Engliſh Tobacco from its having been the firſt introduced here, and being much more hardy than the other ſorts, inſomuch that it has become a weed in many places. It came however originally from America by the name of Petum.

[Sir Walter Raleigh, on his return from America, is ſaid to have firſt introduced the ſmoking of Tobacco into England. *In the houſe* wherein he lived at Iſlington, is his arms, with a Tobacco plant on the top of the ſhield[x]. Parkinſon ſays, that although this kind of Tobacco be not thought ſo ſtrong or ſweet for ſuch as take it by the pipe, yet he had known Sir Walter Raleigh, when he was priſoner in the Tower, make choice of this ſort, to make good Tobacco of, which he knew ſo rightly to cure, as they call it, that it was held almoſt as good as that which came from the Indies, and fully as good as any other made in England[y]. It was cultivated in 1731, by Mr. Miller[z].]

β. N. rugoſa of Miller riſes with a ſtrong ſtalk near four feet high; the leaves are ſhaped like thoſe of the preceding, but are greatly furrowed on their ſurface, and near twice the ſize, of a darker green, and on longer foot-ſtalks. The flowers are of the ſame ſhape, but larger.

[It is remarkable that *Tobacco* has prevailed over the original name *Petum* in all the European languages, with very little variation, and even in Tartary, Japan, &c.—Tobacco is derived from the iſland Tobago. Petume is the Braſilian name.—N. ruſtica is in German, *der Turkiſche Tobak, Baurentabak, Engliſcher,*

wilder or *kleiner Tabak*. In French, *la Nicotiane à feuille ronde & oblongue, petite Nicotiane, Tabac femelle, Faux Tabac, Tabac du Mexique*. In Spanish *Tabaco cimarron*. In Portuguese, *Velembe bastarde*.]

4. The ſtalk of the panicled Tobacco riſes more than three feet high, dividing upwards into many ſmaller panicled branches, which are round and a little hairy. Leaves about four inches long, and three broad, upon pretty long foot-ſtalks. Flowers in looſe panicles at the ends of the branches: tube about an inch long and club-ſhaped; brim ſlightly cut into nine obtuſe reflex ſegments; they are of a yellowiſh green colour, and are ſucceeded by roundiſh capſules.

[Linnæus remarks, that it differs from N. ruſtica in having a more tender, higher, panicled ſtalk; narrower corollas, with a very ſhort blunt border, and a long club-ſhaped tube; and acute calyxes and capſules. Native of Peru. Cultivated in 1739, by Mr. Miller[1]: who ſays that it was found in the valley of Lima by Pere Feuillée, in 1710, and that ſince that the ſeeds were ſent from Peru by the younger Juſſieu to Paris.

[5. Fruſtification in racemes directed one way and revolute, with bell-ſhaped corollas, and cordate leaves like thoſe of N. ruſtica, but crenate, and the whole tree prickly.—Native of South America[2].]

6. Stalk round, near four feet high, ſending out two or three branches from the lower part. Leaves large, heart-ſhaped and a little waved, very clammy, ſtanding upon long foot-ſtalks. Flowers in looſe ſpikes at the top of the ſtalk, of a dull purple colour: calyx unequally cut, one of the ſegments being twice the ſize of the others. The ſeeds were ſent from Peru with the former by the younger Juſſieu. [Cultivated by Mr. Miller in 1739. This and the preceding flower from July to September[3].

According to Linnæus, the leaves are more cordate and glutinous. The flowers in a few long racemes. Corolla almoſt of the following ſpecies, but more unequal and almoſt ringent, gaping at the throat. Stamens bent in towards the upper ſide. One ſegment of the calyx twice as large as the reſt.]

7. This has a pretty thick taper root, which ſtrikes deep in the ground, at the top of it come out ſix or ſeven leaves, ſpreading on the ground, about the ſize of thoſe of the common Primroſe, but of a deeper green. The ſtalk riſes about a foot high, branching into three or four diviſions, at each of which is placed one ſmall leaf. The branches are terminated by a looſe ſpike of flowers, which are ſmall, and of a yellowiſh green colour. This ſort was diſcovered by Dr. Houſtoun at La Vera Cruz, and he ſent the ſeeds to England.

PROPAGATION AND CULTURE.

All the ſorts except ruſtica (*n.* 3.) and paniculata (*n.* 4.) require the ſame culture, and are too tender to grow from ſeeds ſown in the full ground to any degree of perfection in this country, but muſt be raiſed on a hot-bed.

The ſeeds muſt be ſown upon a moderate hot-bed in march, and when the plants are come up fit to remove, they ſhould be tranſplanted into a new hot-bed of a moderate warmth, about four inches aſunder each way, obſerving to water and ſhade them until they have taken root; after which let them have air in proportion to the warmth of the ſeaſon, otherwiſe they will draw up very weak, and be thereby leſs capable of enduring the open air: water them frequently, but while they are very young, it ſhould not be given to them in too great quantities; though when they are pretty ſtrong, they will require to have it often, and in plenty.

In this bed the plants ſhould remain until the middle of may, by which time, if they have ſucceeded well, they will touch each other, therefore they ſhould be inured to bear the open air gradually; after which they muſt be taken up carefully, preſerving a large ball of earth to each root, and planted into a rich light ſoil, in rows four feet aſunder, and the plants three feet diſtance in the rows, obſerving to water them until they have taken root; after which they will require no farther care (but only to keep them clean from weeds) until the plants begin to ſhew their flower-ſtems; at which time cut off the tops of them, that their leaves may be the better nouriſhed, whereby they will be rendered larger, and of a thicker ſubſtance. In auguſt they will be full grown, when they ſhould be cut for uſe; for if they are permitted to ſtand longer, their under leaves will begin to decay. This is to be underſtood for ſuch plants as are propagated for uſe, but thoſe plants which are deſigned for ornament, ſhould be planted in the borders of the pleaſure-garden, and permitted to grow their full height, where they will continue flowering from july, till the froſt puts a ſtop to them.

The third and fourth ſorts are very hardy and may be propagated by ſowing their ſeeds in march, upon a bed of light earth, whence they may be tranſplanted into any part of the garden, and will thrive without farther care.

The three laſt, being ſomewhat more tender than the others, ſhould be ſown early in the ſpring on a hot-bed; when the plants come up, tranſplant them on another moderate hot-bed, water them duly, and give them a large ſhare of free air in warm weather; when the plants have obtained a good ſhare of ſtrength, tranſplant them into ſeparate pots, and plunge them into a moderate hot-bed, to bring them forward. About the middle of june ſome of the plants may be ſhaken out of the pots, and planted in beds of rich earth; but it will be proper to keep one or two plants in pots, to be placed in the ſtove, in caſe the ſeaſon ſhould prove bad, that they may ripen their ſeeds.

[In America, when a regular plantation of Tobacco is intended; the beds being prepared and well turned up with the hoe, the ſeed, on account of its ſmallneſs, is mixed with aſhes, and ſown upon them, a little before the rainy ſeaſon. The beds are raked, or trampled with the feet, to make the ſeed take the ſooner. The plants appear in two or three weeks. So ſoon as they have acquired four leaves, the ſtrongeſt are drawn up carefully, and planted in the field by a line, at the diſtance of about three feet from each plant. If no rain fall, they ſhould be watered two or three times. Every morning and evening the plants muſt be looked over, in order to deſtroy a worm which ſometimes invades the bud. When they are about four or five inches high they are to be cleaned from weeds and moulded up. As ſoon as they have eight or nine leaves, and are ready to put forth a ſtalk, the top is nipped off, in order to make the leaves longer and thicker. After this the buds which ſprout at the joints of the leaves are all plucked, and not a day is ſuffered to paſs without examining the leaves, to deſtroy a large caterpillar, which is ſometimes very deſtructive to them. When they are fit for cutting, which is known by the brittleneſs of the leaves, they are cut with a knife cloſe to the ground; and after lying ſome time, are carried to the drying ſhed or houſe, where the plants are hung up by pairs, upon lines, leaving a ſpace between, that they may not touch one another. In this ſtate they remain to ſweat and dry. When perfectly dry, the leaves are ſtripped from the ſtalks, and made into ſmall bundles, tied with one of the leaves. Theſe bundles are laid in heaps, and covered with blankets. Care is taken not to overheat them, for which reaſon the heaps are laid open to the air from time to time, and ſpread abroad. This operation is repeated till no more heat is perceived in the heaps, and the Tobacco is then ſtowed in caſks for exportation[4].

In China, where the uſe of Tobacco both in ſnuff and for ſmoking is very general, buildings are not thought neceſſary, as they are in the Weſt Indies for curing it; there being little apprehenſion of rain to injure the leaves when plucked. They are hung on cords to dry, without any ſhelter, upon the ſpot in which they grew. Each owner, with his family, takes care of his own produce. This indicates both the nature of the climate little ſubject to moiſture, and the general diviſion of property into minute parcels[5].

[1] Hort. kew. [2] Linn. ſpec. [3] Hort. kew. [4] Long, jam. 3. 719. [5] Staunton, Amb. to China, 2. 175.

Tobacco is cultivated in open fields in ſeveral parts of the Continent of Europe, and might doubtleſs be grown to advantage in England, if it were not prohibited by act of Parliament. This prohibition, which was made for the encouragement of our American colonies, ſtill continues, though the colonies are loſt. Small attempts at planting Tobacco have been made here from time to time, which promiſed ſucceſs. A plantation in the laſt century being found to thrive, Cromwell, probably at the requiſition of the Americans, is ſaid to have ſent a troop of horſe to trample it down.

DESCRIPTION, *&c.*

[Theſe are annual herbaceous plants, with pinnate or bipinnate leaves, and linear leaflets. Flowers terminating, in ſome ſpecies ſurrounded with a five-leaved calyx-like multifid involucre.]

1. This riſes with an upright branching ſtalk a foot and half high. Leaves much longer and finer than thoſe of arvenſis (n. 3.) Flowers large, pale blue, with a five-leaved involucre under each, longer than the flower. They are ſucceeded by larger ſwelling ſeed-veſſels, with five horns at the top. There is a variety with ſingle white flowers, and another with double flowers, which is frequently ſown in gardens, with other annuals for ornament.

[Gærtner deſcribes the capſule as ſimple, ſubglobular, ſubform-five-beaked, five-celled, inflated; that is, the cells being vertically, by means of a very thin, tranſparent, white membrane, divided into a larger empty chamber, and an inner ſmaller one with ſeeds in it. Seeds in each cell about twenty-four, ovate-acuminate, marked with a rib on one ſide, wrinkled, raiſed-dotted, black. Albumen fleſhy, thick, pale-water-coloured. Embryo yellowiſh. Cotyledons ſubfoliaceous. Radicle roundiſh, centripetal.

Native of the South of Europe, among corn. It was cultivated here in 1570, as appears from Lobel. It flowers from june to ſeptember*.

From the fine-cut leaves about the flower it has the names of Fennel-flower, Devil-in-a-buſh, and Love-in-a-miſt. Fennel-flower is become obſolete. Gerarde calls it Damaſke Nigella, from Melanthium damaſcenum of Dodoneus.]

2. This riſes to the ſame height as the preceding. The leaves are not ſo finely cut, and are a little hairy. At the top of each ſtalk is one flower, compoſed of five white petals, which are ſlightly cut at their end into three points; theſe are ſucceeded by oblong ſwelling

* Hort. kew.

seed-veſſels with five horns at the top, filled with ſmall pale-coloured ſeeds. [Gærtner deſcribes the capſule as ſimple, ovate, roundly five-cornered, five-beaked with the permanent filiform ſtyles, rugged with ſcattered callous dots, five-celled, opening at the top inwards. Seeds ovate, acuminate towards the navel, variouſly angular with ſmooth ſharp ribs and wrinkled between them, bay or brown, in a double longitudinal row faſtened to the angle or central margin of the partitions.

Krocker compares it with arvenſis, which it reſembles in ſome degree. The leaves are wider, ſomewhat hairy, green: the ſtem more branched, from a foot to two feet in length, and round: the petals white and ſmaller: the capſules longer, more ſlender at top: more bellying below: the ſeeds aromatic, more acrid, dark-coloured, having a pleaſant ſmell, three-ſided oblong, blunter at one end.

Formerly theſe ſeeds were much in uſe as carminative, ſtimulant and errhine; but this medicine is become deſervedly obſolete. They are ſtill uſed in ſome parts of Germany and Aſia in cookery, inſtead of ſpice, being a pleaſant aromatic [a].

Native of Candia and Egypt. Cultivated in 1658, in the botanic garden at Oxford. It flowers from june to ſeptember [b].

It varies with double flowers. Mr. Miller has two other ſpecies.] N. cretica (n. 4.), riſing with a branching ſtalk a foot high, with ſhorter and broader leaves. At the top of each branch is one flower, without any involucre. Petals oval. Piſtils longer than the petals. Capſule not much ſwollen, and having five ſlender horns at the top. Seeds light yellowiſh brown.—Native of Candia.

N. latifolia riſes with a branching ſtalk a foot high, with leaves like thoſe of Larkſpur. Petals large, oval, entire. It has ten piſtils ſhorter than the petals, and a great number of green ſtamens with blue anthers. The ſeed-veſſels are like thoſe of the preceding. This alſo is a native of Candia.

[This having ten piſtils may poſſibly be a variety of N. hiſpanica.

Gerarde ſays that N. ſativa is called in Engliſh *Gith* and *Nigella romana*; in Cambridgeſhire, *Biſhop's-wort*, and alſo *Saint Katherine's flower*.]

3. This riſes with ſlender ſtalks near a foot high, either ſingle or branching out at the bottom, and having a few very fine-cut leaves, ſomewhat like thoſe of Dill. Each branch is terminated by one ſtar-pointed flower, of a pale blue colour, without any leafy involucre. They are ſucceeded by capſules, having five ſhort horns, inclining different ways at the top, and are filled with rough black ſeeds. There is a variety with white flowers; and another with double flowers.

[In this the capſule is narrower below, contrary to what it is in the preceding. The germs and ſtyles vary in number from five to ſeven. The ſeeds are ſometimes uſed inſtead of thoſe of N. ſativa; but they are not ſo aromatic, nor have they the ſame pleaſant ſmell [c].

Native of Germany, France, Italy, Carniola, Switzerland. Cultivated here in 1713. It flowers from june to ſeptember [d].]

4. This riſes near a foot and half high. The lower leaves are finely cut; but thoſe on the ſtalks are cut into broader ſegments. The flowers are larger than thoſe of the other ſpecies, and of a fine blue colour, with green veins at the back. Nectaries of a ſea-green colour. The piſtils are of equal length with the petals: they with the ſtamens are of a deep purple or puce colour. The capſule has five horns, and is of a firmer texture than any of the other. It grows naturally in Spain and the South of France: and there is a variety of it with double flowers.

[It appears from Parkinſon, that it was cultivated here in 1629. It flowers from june to ſeptember [e].]

5. This riſes with a branching ſtalk a foot and half high; with pretty long leaves, finely divided. The flowers are produced at the end of the branches: the petals are yelloviſh; at the baſe of theſe are placed eight nectaries, between which ariſe a great number of ſtamens, with an unequal number of germs, from five to eight or nine, oblong and compreſſed. The capſules are joined together on their inner ſide, terminate in horns, open longitudinally, and contain many thin compreſſed ſeeds, having borders round them.—Mr. Miller has figured only five.

[Gærtner thus deſcribes them: Capſules compound of eight or ten leguminous partial capſules, connected below above the middle, free or diſtinct above, and moderately diverging, wrinkled and angular on one ſide, compreſſed and ſmooth on the other, ending in a compreſſed beak, and opening at the inner future. Seeds rounded, compreſſed, brown, ſurrounded by a wide membranaceous rim. Albumen much narrower than the margin, fleſhy, pale, inodorous. Embryo ſubcompreſſed, linear, milky. Cotyledons ſhort. Radicle relatively centripetal.

Native of Syria, as in corn fields about Aleppo. Cultivated in 1731, by Mr. Miller. It flowers from july to ſeptember [f].]

PROPAGATION AND CULTURE.

All theſe plants may be propagated by ſowing their ſeeds upon a bed of light earth, where they are to remain (for they ſeldom ſucceed well if tranſplanted;) therefore, in order to have them intermixed amongſt other annual flowers in the borders of the flower-garden, the ſeeds ſhould be ſown in patches at proper diſtances; and when the plants come up, you muſt pull up thoſe which grow too cloſe, leaving but three or four of them in each patch, obſerving alſo to keep them clear from weeds, which is all the culture they require. In july they will produce their flowers, and their ſeeds will ripen in auguſt, when they ſhould be gathered and dried; then rub out each ſort ſeparately, and preſerve them in a dry place.

The ſeaſon for ſowing theſe ſeeds is in march, but if you ſow ſome of them in auguſt, ſoon after they are ripe, upon a dry ſoil and in a warm ſituation, they will abide through the winter, and flower ſtrong the ſucceeding year; by ſowing the ſeeds at different times, they may be continued in beauty moſt part of the ſummer.

They are all annual plants, periſhing ſoon after they have perfected their ſeeds; which, if permitted to ſcatter upon the borders, will come up without any farther care.

The varieties with double flowers are chiefly ſown in flower gardens: thoſe with ſingle flowers are rarely admitted into any but botanic gardens. The third ſort, having leſs beauty than the others, is alſo ſeldom found in flower-gardens. The firſt and fourth are moſt commonly cultivated with us.

DESCRIPTIONS, *&c.*

1. This is an inelegant tree, twelve feet high, the branches of which, being often weak and bending, require a ſupport. Leaves deciduous, pinnate or ternate, having two leaflets on a ſide or one only with an odd one, ovate, bluntly acuminate, quite entire, ſhining, thin, the end one largeſt, the inner ones ſmaller, oppoſite or alternate. Spikes compound and denſe, four inches long, terminating and axillary, from each bud before the leaves ſpring forth, and frequently alſo on the older branches. Flowers ſmall, ſeſſile, without ſcent, and almoſt without colour, numerous. Seed only one in the germ.—Native of Carthagena in New Spain every where in the woods, flowering in july and auguſt.

2. This is a thornleſs ſhrub, with numerous twining ſtems and branches climbing the trees to the height of fifteen feet. Leaves numerous, alternate, pinnate, ſubvilloſe, three or four inches long, having two leaflets on each ſide, and an odd one; theſe are ſubovate, quite entire, blunt iſh with a ſmall briſtle-ſhaped point, ſmooth, petioled, an inch and half long. Common peduncles ſhort, many-flowered, numerous, on the younger branchlets axillary, and at the ſame time at their extremities coming out from naked tubercles, making all together a leafy panicle, often a foot long, and handſome. Flowers peduncled, ſmall, yellow, inodorous.—Native of Carthagena in woods and copſices; flowering in ſeptember [a].

Jacquin would not oppoſe any one who ſhould make two diſtinct genera of theſe two ſpecies. Cultivated in 1766, by Robert James Lord Petre [a].]

DESCRIPTION, *&c.*

There are two varieties of this ſhrub: one in the ſqualid nitro-ſaline parts of the deſert extending from the north of the Caſpian; ſcarcely beyond the fiftieth degree of latitude; with the ſtems almoſt upright, almoſt unarmed, and larger in all its parts. The other in the ſalt plains of Siberia, between the Irtis and Ob rivers, by the ſalt lakes near the Jeniſea, and in the regions beyond the lake Baikal; proſtrate, thorny, ſmaller and more tender in all its parts.

The firſt, or Caſpian variety, which is what Schober deſcribed, riſes with ſeveral ſtems that are an ell in height, ſuberect or ſupine, from a thick woody root, covered with a whitiſh gray bark, ſpineſcent at the end, as are alſo the branches, and briſtle. Branchlets alternate, chiefly directed one way, whiter, leafed alternately, dichotomous and floriferous at top. Leaves

[b] Thunberg.

[a] Jacquin. [a] Hort. kew.

in alternate buds, up to the flowers, ſeſſile in bundles, four or five together, fleſhy, ſucculent, oblong, attenuated at the baſe, quite entire, glaucous green. In the autumn, and in drying the plant, they very eaſily fall off, leaving a duſky ſpot at the place. They appear to be very ſmooth; but when examined by a glaſs they are found to have very fine proſtrate hairs ſcattered over them. The terminating cymes of the branchlets are dichotomous, naked, hairy, faſtigiate; the extremities bear three or four ſeſſile flowers, pointing the ſame way, and forming a ſort of ſpike. Perianth in the flower ſcarcely viſible, conſiſting of five thick toothlets ſurrounding the receptacle; in the fruit more evident, and ſomewhat bell-ſhaped. Petals white, ſpreading very much, concave, blunt and cowled at the end, with a ſlender toothlet turned towards the centre of the flower. Stamens twelve to fifteen, the length of the corolla: anthers oblong, yellow, bifid at the baſe. Germ conical, terminated by a ſeſſile, awnleſs, tripapillar ſtigma. The young fruit is conical, ſubacuminate with the ſtigma produced, with more frequent proſtrate hairs ſcattered over it than the other parts of the plant. Drupe when ripe conical-convex, ſucculent, dark red, when drier black and dying a dark blue, ſaltiſh, and never to be entirely dried. Nut conical, very ſharp, convex at the baſe, and having about a dozen little holes in it; at the top as it were ſix-valved, but with the valves united into one point, alternately very narrow and linear. Nucleus not three-celled, but ſimple, cylindric, continued to the very tip of the nut, yellow, ſweetiſh, covered with a yellow ſtriated aril. The cymes, when the fruit falls, continue and ſhrivel up, whence the ſhrub becomes in a manner thorny; and ſometimes when the branches of the cyme fall off, a genuine ſpine comes out.

The ſecond or Siberian variety, which Steller and Gmelin chiefly obſerved, from a woody root, frequently exhibits a large knob or tuber, ſometimes as big as the human head, warted and veined; from this twenty and more ſtems ſpread in a ring, they are proſtrate and even preſſed cloſe to the ground, a foot and half in length, with the branches moſt elegantly diſpoſed like a winged leaf. The ſtems are more ſlender than in the preceding, more elongated, ſtraighter, whitiſh gray, with the branches alternate, ſpreading very much, lying on the ground: from theſe branchlets grow upwards, on the older ones commonly ſpineſcent, and only leafy; but the younger branches have generally dichotomous flowering cymes. The leaves are much ſmaller than the Caſpian plant, very like them in form, or more ſucculent and ſalt. Cymes ſmaller, cloſer, and more hairy. Flower in all its parts ſmaller, but the calyx more evident. The incipient fruit as in the other; but the ripe drupe much ſmaller, ſtaining paper of a very dark blue. Nut by no means conical-acuminate, but ovate, and ſubtrigonal, which the Caſpian nut is not; it has however the ſix grooves approximating by pairs, and the little holes, which are ſometimes indeed ſcarcely viſible.

In the fat very ſalt lands by the lake Koræкofſkoi in Siberia, Profeſſor Pallas obſerved ſhrubs of Nitraria that were much ſtouter, with the ſtems almoſt equal to the Caſpian variety; the leaves wider, five from each bud, ſometimes entire, ſometimes variouſly cut. Not having an opportunity of obſerving it in flower, he could not determine what other differences there might be between this and the others.

Murray has given a full length deſcription of this rare ſhrub, but I have preferred the above from Pallas, becauſe it is poſterior to Murray's, and made from wild plants, not diſtorted and changed by culture.

Pallas informs us, that the berries, though ſaltiſh and inſipid, are eaten in the Caſpian deſert, but in that arid ſoil they are almoſt the only luxury. Camels feed on the twigs. The Ruſſians near the Caſpian call this ſhrub *Samoniecka*, and the Turcomans *Siegak*.

Both the varieties deſcribed above ſeem, from Chevalier Murray's account, to have been in the botanic garden at Gottingen; one of them flowered there, and Murray's deſcription was made from that plant. Linnæus had the ſhrub twenty years before it flowered in Sweden; and during ten years having in vain tried to make it flower in the garden at Upſala, he at length ſucceeded by watering the plant with ſalt water; it flowered however at Gottingen without this aſſiſtance. Murray expreſſes a ſurpriſe that it has not been uſed in its native ſoil for making Soda: but perhaps it does not grow in ſufficient quantity, or there may be an ample harveſt in that ſalt region, of plants that anſwer the ſame purpoſe.

DESCRIPTION, *&c.*

Root annual, ſimple, filiform, often three feet long, blackiſh. Stem a foot long, herbaceous, proſtrate, roundiſh, very ſmooth, with white dots ſcattered over it. Branches alternate, the lower ones the length of the ſtalk. Leaves alternate, two together, reflex, rhomb-ovate, quite entire, blunt, ſomewhat fleſhy, an inch long, ſomewhat papuloſe, even, flat, veined, unequal, alternately larger and ſmaller.] Miller remarks, that they come out ſingle at ſome joints, by pairs at others, and frequently three or four at the upper joints. [Petioles ancipital, ſcarcely ſhorter than the leaves, ſmooth, thoſe belonging to the upper leaves vaguely ciliate. Pedúncles lateral, ſolitary, ſpreading a little, an inch long, one-flowered, round, thicker at top, hairy. Flowers inferior. Corolla of a fine blue colour, with dark purple veins at the throat: calyx pale purple: filaments purple; anthers blackiſh-blue; piſtil white, with a black germ: receptacle red. The ſtem and petioles are green with purple ſpots. The leaves are dark green*.

Linnæus and others conſider this plant as having no pericarp, but five ſeeds covered with a juicy rind. Gærtner deſcribes them as drupes, decumbent in the baſin of the calyx, ſmall, fleſhy, ovate-acuminate, black, convex above, ſomewhat angular below, and

* Linn. dec.

punched

punched with umbilical pores. Rind thin, fleshy, dark-purple. Shell bony, excavated with three or five very polished cells, not opening. According to Linnæus they have from two to four cells: but Gærtner remarks, that the number of cells varies, three or four however being the most frequent number, and that he never saw six, except in Schmidel's figure.—Common receptacle in the fleshy bottom of the calyx, to which the drupes radiating from the centre and lying horizontally are fastened: proper none, except the little umbilical scars at the base of the drupe. Seeds solitary, rounded, beaked, lenticular-compressed, very minutely dotted, white[t].

Linnæus placed it among the *Asperifoliæ*, observing however that it has no less affinity to the *Luridæ*. Jussieu remarks, that it has the appearance of Convolvulus; the leaves alternate, and as in the *Solaneæ* geminate; with the flowers extraaxillary; and that it is allied to the *Borragineæ* by its five-capsuled fruit, but that in habit and flower it more resembles the *Solaneæ* and *Convolvuli*. Gærtner is decidedly of opinion that Nolana should range in the order of *Solanaceæ*.

The seeds of Nolana were sent to Linnæus by David van Royen, professor of Botany at Leyden, in the spring of the year 1761, under the name of Belladonna. Its native country was not known; but was conjectured to be Spain. It proves however to be Peru. Mr. Miller cultivated it in 1761[s]. He says that he received the seeds from Mr. Forskahl, one of the persons who were sent by the late King of Denmark, to make discoveries in the east; and thence concludes erroneously that it grows naturally in Egypt. It flowers in july, and the seeds ripen in september.

PROPAGATION AND CULTURE.

Sow the seeds on a hot-bed in march. When the plants are fit to remove, transplant them singly into small pots filled with light earth, and plunge them into a fresh hot-bed to bring the plants forward, otherwise they will not ripen their seeds in this country. When their flowers open in july, they should have a large share of air admitted to them, when the weather is warm, to prevent their flowers from falling away without producing seeds. With this management the plants will continue flowering till the early frosts destroy them, and ripe seeds will be produced in the beginning of september.

NURSERY, or Nursery-garden, is a piece of land set apart for the raising and propagating all sorts of trees and plants to supply the gardens and plantations. Of this sort there are a great number in the different parts of this kingdom, but particularly in the neighbourhood of London, which are occupied by the gardeners, whose business it is to raise trees, plants, and flowers for sale; and in many of these there is at present a much greater variety of trees and plants cultivated, than can be found in any other part of Europe. In France, their Nurseries, (which are but few, when compared with those in England) are chiefly confined to the propagation of fruit-trees, whence they have the appellation of Pepinier. For there is scarce any of those gardens, where a person can be supplied with evergreens, flowering-shrubs, or forest-trees: and in Holland their Nurseries are principally for flowers; some few of them, indeed, propagate tender exotic plants. But Nurseries in the neighbourhood of London include all these, and hence most of the curious persons abroad are supplied with furniture for their gardens. But I do not propose in this place, to treat of these extensive Nurseries, or to give a description of them, therefore shall confine myself to treat of such Nurseries only as are absolutely necessary for all lovers of planting, to have upon the spot where they design to make their plantation. For if these are large, the expense of carrying a great number of trees, if the distance is great, will be no small article, beside the hazard of their growing; which, when the plants have been trained up in good land, and removed to an indifferent one, is very great. Therefore it is of the utmost consequence to every planter to begin by making a Nursery. But in this article I must beg leave to observe, that a Nursery should not be fixed to any particular spot: I mean by this, that it would be wrong to continue the raising of trees any number of years upon the same spot of ground, because hereby the ground will be so much exhausted by the trees, as to render it unfit for the same purpose. Therefore all good Nursery gardeners shift and change their land from time to time, for when they have drawn off the trees from a spot of ground, they plant kitchen herbs, or other things, upon the ground for a year or two; by which time, as also by dunging and trenching the land, it is recovered, and made fit to receive other trees. But this they are obliged to from necessity, being confined to the same land; which is not the case with those gentlemen, who have large extent of ground in the country. Therefore I would advise all such persons to make Nurseries upon the ground which is intended for planting, where a sufficient number of the trees may be left standing, after the others have been drawn out to plant in other places; which, for all large growing trees, but particularly such as are cultivated for timber, will be found by much the most advantageous method; for all those trees which come up from the seed, or which are transplanted very young into the places where they are designed to remain, will make a much greater progress, and become larger trees, than any of those which are transplanted at a greater age. Therefore the Nurseries should be thinned early, by removing all those trees which are intended for other plantations while they are young, because hereby the expense and trouble of staking, watering, &c. will be saved, and the trees will succeed much better. But in exposed situations, where these are Nurseries made, it will be necessary to permit the trees to stand much longer; that, by growing close together, they may shelter each other, and draw themselves up; and these should be thinned gradually, as the trees advance; for, by taking away too many at first, the cold will check the growth of the remaining trees. But then those trees which are taken out from these Nurseries, after a certain age, should not be depended on for planting; and it will be prudence rather to consign them for fuel, than to attempt to remove them large, whereby, in endeavouring to get them up with good roots, the roots of the standing trees will be often much injured.

What has been here proposed, must be understood for all large plantations in parks, woods, &c. but those Nurseries which are only intended for raising evergreens, flowering shrubs, or plants which are designed to embellish gardens, may be confined to one spot, because a small compass of ground will be sufficient for this purpose. Two or three acres of land employed this way, will be sufficient for the most extensive designs, and one acre will be full enough for those of moderate extent. And such a spot of ground may be always employed for sowing the seeds of foreign trees and plants, as also for raising many sorts of biennial and perennial flowers, to transplant into the borders of the pleasure garden, and for raising many kinds of bulbous-rooted flowers from seeds, whereby a variety of new sorts may be obtained annually, which will recompense for the trouble and expense,

[t] Gærtner. [s] Hort. kew.

penſe, and will moreover be an agreeable diverſion to all thoſe perſons who delight in the amuſements of gardening.

Such a Nurſery as this ſhould be conveniently ſituated for water; for where that is wanting, there muſt be an expenſe attending the carriage of water in dry weather. It ſhould alſo be as near the houſe as it can with conveniency be admitted, in order to render it eaſy to viſit at all times of the year, becauſe it is abſolutely neceſſary that it ſhould be under the inſpection of the maſter, for unleſs he delights in it, there will be little hopes of ſucceſs. The ſoil of this Nurſery ſhould alſo be good, and not too heavy and ſtiff, for ſuch land will be very improper for ſowing moſt ſorts of ſeeds; becauſe as this will detain the moiſture in the ſpring and winter, the ſeeds of moſt tender things, eſpecially of flowers, will rot in the ground, if ſown early; therefore where perſons are confined to ſuch land, there ſhould be a good quantity of ſand, aſhes, and other light manures buried, in order to ſeparate the parts, and pulverize the ground; and if it is thrown up in ridges, to receive the froſt in winter, it will be of great uſe to it, as will alſo the frequent forking, or ſtirring of the ground, both before and after it is planted.

The many advantages which attend the having ſuch a Nurſery, are ſo obvious to every perſon who has turned his thoughts in the leaſt to this ſubject, that it is needleſs for me to mention them here; and therefore I ſhall only beg leave to repeat here what I have ſo frequently recommended, which is, the carefully keeping the ground always clean from weeds; for if theſe are permitted to grow, they will rob the young trees of their nouriſhment. Another principal buſineſs is, to dig the ground between the young plants at leaſt once every year, to looſen it for the roots to ſtrike out; but if the ground is ſtiff, it will be better if it is repeated twice a year, viz. in october and march, which will greatly promote the growth of the plants, and prepare their roots for tranſplanting.

But there may be ſome perſons who have the curioſity to raiſe their own fruit-trees, which is what I would recommend to every one who is a lover of good fruit, becauſe the uncertainty in procuring the intended kinds of each fruit is very great, when taken from common Nurſery-gardens, ſo that moſt gentlemen who have planted many, have conſtantly complained of this diſappointment; but beſides this, there is another inconvenience, which, for want of ſkill, is ſcarce taken notice of, which is, the taking the buds or grafts from young trees in the Nurſeries which have not borne fruit; this having been frequently repeated, renders the trees ſo raiſed as luxuriant as Willows, making ſhoots to the top of the walls in two or three years, and are rarely after fruitful with the moſt ſkilful management: I ſhall therefore treat of the proper method to make a Nurſery of theſe trees.

In the doing which the following rules muſt be obſerved:

1. That the ſoil in which you make the Nurſery be not better than that where the trees are to be planted out for good; the not obſerving this is the reaſon that trees are often at a ſtand, or make but little progreſs for three or four years after they come from the Nurſery, as it commonly happens to ſuch trees as are raiſed near London, and carried into the northern parts of England, where, being planted in a poor ſoil and a much colder ſituation, the trees ſeldom ſucceed well; therefore it is by far the better method (when you have obtained the ſorts you would propagate) to raiſe a Nurſery of the ſeveral ſorts of ſtocks proper for the various kinds of fruit, upon which you may bud or graft them; and thoſe trees which are thus raiſed upon the ſoil, and in the ſame degree of warmth, where they are to be planted, will ſucceed much better than thoſe brought from a greater diſtance and from a richer ſoil.

2. This ground ought to be freſh, and not ſuch as has been already worn out by trees, or other large growing plants, for in ſuch ſoil your ſtocks will not make any progreſs.

3. It ought not to be too wet, nor over dry, but rather of a middling nature; though of the two extremes, dry is to be preferred, becauſe in ſuch ſoils (though the trees do not make ſo great a progreſs as in moiſt, yet) they are generally ſounder, and more diſpoſed to fruitfulneſs.

4. You muſt alſo obſerve to incloſe it, that cattle and vermin may not come in, for theſe will make ſad havock with young trees, eſpecially in winter, when the ground is covered with ſnow, that they have little other food which they can come at. Some of the moſt miſchievous of theſe animals are hares and rabbets, which are great deſtroyers of young trees at that ſeaſon, by eating of all their bark; therefore you muſt carefully guard your Nurſery againſt theſe enemies.

The ground being incloſed, ſhould be carefully trenched about eighteen inches, or two feet deep, provided it will allow it; this ſhould be done in auguſt or ſeptember, that it may be ready to receive young ſtocks at the ſeaſon for planting, which is commonly in the middle or end of october. In trenching the ground, you muſt be very careful to cleanſe it from the roots of all noxious weeds, ſuch as Couch-graſs, Docks, &c. which, if left in the ground, will get in among the roots of the trees, ſo as not to be gotten out afterwards, and will ſpread and over-run the ground, to the great prejudice of your young ſtocks.

After having dug the ground, and the ſeaſon being come for planting, you muſt level down the trenches as equal as poſſible, and then lay out the ground into quarters, proportionable to the ſize thereof, and thoſe quarters may be laid out in beds, for the ſowing of ſeeds or the ſtones of fruit.

The beſt ſort of ſtocks for Peaches, Nectarines, &c. are ſuch as are raiſed from the ſtones of the Muſcle and white Pear Plumb, but you ſhould never plant ſuckers of theſe (which is what ſome people practiſe) for theſe ſeldom make ſo good ſtocks, nor are ever well-rooted plants; beſides, they are very ſubject to produce great quantities of ſuckers from their roots, which are very troubleſome in the borders, or walks of a garden, and greatly injure the tree; ſo that you ſhould annually, or at leaſt every other year, ſow a few ſtones of each, that you may never be at a loſs for ſtocks.

For Pears, you ſhould have ſuch ſtocks as have been raiſed from the kernels of the fruit where perry has been made, or elſe preſerve the ſeeds of ſome ſorts of ſummer Pears, which generally ſhoot ſtrong and vigorous, as the Cuiſſe Madame, Windſor, &c. but when this is intended, the fruit ſhould be ſuffered to hang upon the trees till they drop, and afterward permitted to rot; then take out the kernels and put them in ſand, being careful to keep them from vermin, as alſo to place them where they may not be too damp, which will cauſe them to grow mouldy. Theſe you ſhould ſow for ſtocks early in the ſpring, upon a bed of good light freſh earth, where they will come up in about ſix weeks, and, if kept clear from weeds, will be ſtrong enough to tranſplant the october following. But for many ſorts of ſummer and autumn Pears, Quince ſtocks are preferable to free (i. e. Pear) ſtocks; theſe are generally uſed for all the ſorts of ſoft-melting Pears, but they are not ſo good for the breaking Pears, being apt to render thoſe fruits which are grafted upon them ſtony; theſe are very often propagated from ſuckers, which are generally produced in plenty from the roots of old trees; but thoſe are not near ſo good as ſuch as are propagated from cuttings or layers, which have always much better roots, and are not ſo ſubject to produce ſuckers as the other, which is a very deſirable quality, ſince theſe ſuckers do not only rob the trees of part of their nouriſhment, but are very troubleſome in a garden.

Apples are graſted or budded upon ſtocks raiſed from ſeeds which come from the cyder-preſs, or upon Crab ſtocks, the latter of which are eſteemed for their durableneſs, eſpecially for large ſtandard trees; theſe ſhould be raiſed from ſeeds, as the Pear ſtock, and muſt be treated in the ſame manner, for thoſe procured

cured from ſuckers, &c. are not near ſo good; but for ſmall gardens, the Paradiſe ſtock has been for ſome years paſt greatly eſteemed, it being of very humble growth, cauſes the fruit-trees grafted or budded thereon to bear very ſoon, and they may be kept in ſmall compaſs; but theſe are only proper for very ſmall gardens, or by way of curioſity, ſince the trees thus raiſed are but of ſhort duration, and ſeldom ariſe to any ſize to produce fruit in quantities, unleſs the graft or bud be buried in planting, ſo that they put forth roots, and then they will be equal to trees grafted upon free ſtocks, ſince they receive but ſmall advantage from the ſtock.

For Cherries, you ſhould make uſe of ſtocks raiſed from the ſtones of the common Black, or the wild Honey Cherry, both of which are ſtrong free growers, and produce the cleaneſt ſtocks.

For Plums, you may uſe the ſtones of moſt free-growing ſorts, which will alſo do very well for Apricots, theſe being not ſo difficult to take as Peaches or Nectarines; but (as I ſaid before) theſe ſhould not be raiſed from ſuckers for the reaſon there aſſigned, but rather from ſtones.

There are ſome perſons who recommend the Almond ſtock for ſeveral ſorts of tender Peaches, upon which they will take much better than upon Plum ſtocks; but theſe being tender in their roots, and apt to ſhoot early in the ſpring, and being of ſhort duration, are by many people rejected; but ſuch tender ſorts of Peaches which will not take upon Plum ſtocks, ſhould be budded upon Apricots, upon which they will take very well; and all ſorts of Peaches which are planted upon dry ſoils, will continue much longer, and not be ſo ſubject to blight, if they are upon Apricots; for it is obſerved, that upon ſuch ſoils where Peaches ſeldom do well, Apricots will thrive exceedingly, which may be owing to the ſtrength and compactneſs of the veſſels in the Apricots, which render it more capable of aſſimilating, or drawing its nouriſhment from the Plum ſtock, which in dry ſoils ſeldom afford it in great plenty to the bud; and the Peach-tree being of a looſe ſpongy nature, is not ſo capable to draw its nouriſhment therefrom, which occaſions that weakneſs which is commonly obſerved in thoſe trees, when planted on a dry ſoil; therefore it is the common practice of the Nurſery-gardeners, to bud the Plum ſtocks either with Apricots, or ſome free growing Peach; and after theſe have grown a year, they bud the tender ſorts of Peaches upon theſe ſhoots, by which method many ſorts ſucceed well, which in the common way will not thrive, or ſcarce keep alive; and theſe the gardeners term double worked Peaches.

There are ſome people who of late have budded and grafted Cherries upon ſtocks of the Cornith, and others on the Morello Cherry, which, they ſay, will render the trees more fruitful, and leſs luxuriant in growth, ſo that they may be kept in leſs compaſs; theſe ſtocks having the ſame effect upon Cherries, as the Paradiſe ſtock has on Apples.

Having provided yourſelf with young ſtocks of all theſe different ſorts, which ſhould be raiſed in the ſeminary the preceding year, you ſhould proceed to tranſplanting them in October (as was before directed) into the Nurſery. The diſtance which they ſhould be planted, if deſigned for ſtandards, ſhould be three feet and a half or four feet, row from row, and a foot and a half diſtant in the rows; but if for dwarfs, three feet row from row, and one foot in the rows, will be a ſufficient diſtance.

In taking theſe ſtocks out of the ſeed-beds, you muſt raiſe the ground with a ſpade, in order to preſerve the roots as entire as poſſible; then with your knife prune off all the very ſmall fibres; and if there are any which have a tendency to root downright, ſuch roots ſhould be ſhortened; having thus prepared the plants, draw a line acroſs the ground intended to be planted, and with your ſpade open a trench thereby exactly ſtraight, into which place them at the diſtance before-mentioned, ſetting them exactly upright; and then put the earth in cloſe to them, filling up the trench, and with your foot preſs the earth gently to the roots of them, obſerving not to diſplace them ſo as to make the rows crooked, which will render them unſightly; theſe plants ſhould by no means be headed, or pruned at top, which will weaken them, and cauſe them to produce lateral branches, and thereby ſpoil them.

If the winter ſhould prove very cold, it will be of great ſervice to your young ſtocks, to lay ſome mulch upon the ſurface of the ground near their roots, which will prevent the froſt from penetrating the ground, ſo as to hurt the tender fibres which were produced after planting; but you ſhould be careful not to let it lie too thick near the ſtems of the plants, nor remain too long, leſt the moiſture ſhould be prevented from penetrating to the roots of the plants, which is often does, where there is not due care taken to remove it as ſoon as the froſt is over.

In the ſummer ſeaſon hoe and deſtroy the weeds, which, if permitted to remain in the Nurſery, will greatly weaken and retard the growth of your ſtocks; and, the ſucceeding years, obſerve to dig up the ground every ſpring between the rows, which will looſen it ſo, as that the fibres may eaſily ſtrike out on each ſide, and the weeds will thereby be deſtroyed; alſo where any of the ſtocks have ſhot out lateral branches, prune them off, that they may be encouraged to grow upright and ſmooth.

The ſecond year after planting, ſuch of the ſtocks as are deſigned for dwarf trees will be fit to bud, but thoſe which are deſigned for ſtandards, ſhould be ſuffered to grow ſix or ſeven feet high before they are budded or grafted. The manner of budding and grafting being fully deſcribed under their reſpective heads, I ſhall not repeat them in this place, nor need I ſay any thing more of treating theſe trees after budding, that being alſo treated of under the ſeveral articles of fruits; I ſhall only add, that thoſe ſtocks which were budded in the ſummer, and have failed, may be grafted the following ſpring, but Peaches and Nectarines never take well from grafts, theſe ſhould therefore be always budded.

The ground you intend for the Flower-nurſery ſhould be well ſituated to the ſun, but defended from ſtrong winds, by plantations of trees or buildings, and the ſoil ſhould be light and dry; which muſt always be obſerved, eſpecially for bulbous-rooted flowers, which are deſigned to be planted therein, the particulars of which are exhibited under the ſeveral articles of flowers.

In this Nurſery ſhould be planted the offsets of all your bulbous-rooted flowers, where they are to remain until they become blowing roots, when they ſhould be removed into the pleaſure-garden, and planted either in beds or borders, according to the goodneſs of the flowers, or the management which they require.

You may alſo in this ground raiſe the ſeveral ſorts of bulbous-rooted flowers from ſeed, by which means new varieties may be obtained; but moſt people are diſcouraged from ſetting about this work, from the length of time before the ſeedlings will come to flower: however, after a perſon has once begun, and conſtantly continued ſowing every year, after the parcel firſt ſown has flowered, the regular ſucceſſion of them coming annually to flower, will not render this method ſo tedious as it at firſt appeared.

The ſeedling Auriculas, Polyanthuſes, Ranunculuſes, Anemonies, Carnations, &c. ſhould be raiſed in this Nurſery, where they ſhould be preſerved until they have flowered, when you ſhould mark all ſuch as are worthy of being tranſplanted into the flower-garden, which ſhould be done in their proper ſeaſons; for it is not ſo well to have all theſe ſeedling flowers expoſed to public view in the flower-garden, becauſe it always happens, that there are great numbers of ordinary flowers produced amongſt them, which will make but an indifferent appearance in the pleaſure-garden.

[For a Nurſery, Dr. Hunter recommends a rich deep and ſtiffiſh mould, though the trees ſhould afterwards be removed into a poorer ſoil. Reaſon, ſays he, teaches that young trees growing luxuriantly and freely in a good ſoil will form vigorous and healthy roots,

and when they come to be afterwards planted in worſe land, they will be able, from the ſtrength of their conſtitution, to feed themſelves freely with coarſer food. On the contrary young trees, raiſed upon poor land, by having their veſſels contracted, and their outward bark moſſy and diſeaſed, will be a long time, even after being removed to a rich ſoil, before they attain to a vigorous ſtate. Having fixed upon a proper place of ſufficient ſize for the purpoſe, fence it with hedges, pales or walls, to keep out cattle, hares and rabbets: then in october or november trench the land two ſpits deep, and in ſpring turn it over again: after which let the ſurface be laid ſmooth, and ſet out into quarters[1].

A very judicious planter, adds Dr. Hunter, recommended to him the following method of making a Seminary or Nurſery for foreſt trees.

Trench the ground in november eighteen inches deep, if the ſoil will admit of it; but where the ſtaple is too thin one foot will be ſufficient, in which caſe the ſward muſt be pared off very thin, and laid in the bottom of the trench. The following year let this land be cultivated with a crop of cabbages, turneps or rape, which muſt be eat off with ſheep. After this a common digging will be ſufficient, previous to its being formed into beds for the reception of the ſeeds. The urine of ſheep is one of the moſt cheriſhing manures for all plants raiſed in a Seminary or Nurſery[2].

The ſoil of the Nurſery, according to Mr. Marſhall, ſhould be rich and deep, and ſhould be prepared by double diggings and ſuitable meliorations: if not deep and rich by nature, it muſt be made ſo by art: for if the roots of the tender plants have not a ſoil they affect, or ſufficient room to ſtrike in, there will be little hope of their furniſhing themſelves with that ample ſtock of fibres which is neceſſary to a good plant, and with which it is the principal uſe of the Nurſery to ſupply them.

The ſituation of the Nurſery is determined by the ſoil or by local conveniences: the nearer it is, the more attendance will probably be given it; but the nearer it lies to the ſcene of planting, the leſs carriage will be requiſite.

In pruning ſeedlings, layers and ſuckers for the Nurſery, the roots ſhould not be left too long, but trimmed off pretty cloſe, to form a ſaug globular root. By this means the new fibres will be formed immediately round the main root, and may of courſe eaſily be removed with it, without diſturbing the earth interwoven among them. The tops ſhould, in moſt caſes, be trimmed cloſe up to the leader; or, if awkward or defective, be cut off a little above the root.

Various methods are practiſed for putting in ſeedlings: by the dibble, by the ſcoop, by a ſingle chop with the ſpade, by two chops one acroſs the other, by ſquare holes made by four chops of the ſpade, bringing up the mould with the laſt, or by bedding, a method chiefly made uſe of for quickſets. The chief art in putting them in lies in not cramping the fibres of the roots, but letting them lie free and eaſy in the mould: the particular mode or inſtrument to be made uſe of, depends much upon the ſize of the plants to be put in. This alſo determines, in a great meaſure, the proper diſtance between the rows and between plant and plant. The propoſed method of cleaning too is a guide to the diſtance. The natural tendency of the plant itſelf muſt alſo be conſidered. From ſix to twenty-four inches in the rows, with intervals from one to four feet wide, will comprehend the whole variation of diſtances.

Pruning is neceſſary, to prevent the plants from crowding each other, and to give them ſtem. Shrubs, which do not require a ſtem, ſhould be planted in a quincunx, that they may ſpread every way; but foreſt trees, and trees in general, require ſome length of ſtem; and in giving them this, the leading ſhoot is more particularly to be attended to. If the head be double, one of the ſhoots muſt be taken cloſe off: if it be maimed or defective, it may be well to cut the plant down to the ground, and train a freſh ſhoot, or if the head be taken off ſmooth, immediately above a ſtrong ſide ſhoot, this will ſometimes outgrow the crookedneſs, and in a few years become a ſtraight plant.

The time of the plants remaining in the Nurſery is determined by a variety of circumſtances; and a ſeaſonable thinning frequently becomes neceſſary. The general rule for this is, to thin as ſoon as the tops or roots interfere.

In taking up trees and ſhrubs for the purpoſe of planting them out where they are to ſtand, every root and fibre ought, as much as poſſible, to be preſerved; and therefore no violence ſhould be uſed in this operation. The beſt way is to dig a trench cloſe by the ſide of the plant, and having undermined the roots, to let it fall of itſelf, or with a very little aſſiſtance into the trench: if any roots ſtill have hold, cut them off with a ſharp inſtrument, ſo as to tear the main root as little as may be. If the root was properly pruned before planting, it will now turn out a globular bundle of earth and fibres.

When the Nurſery lies at a diſtance from the plantations, much depends upon packing the plants judiciouſly. Valuable plants are ſent in pots or baſkets. Straw however is uſed in general, and will ſufficiently protect them both from froſt and drought; eſpecially if for the latter purpoſe, the ſtraw be occaſionally moiſtened with water[3]. Moſs is the moſt effectual for keeping the roots moiſt and ſuppli in diſtant carriage.

Branches round hirſute, leaves cordate pubeſcent on both ſides.

DESCRIPTIONS, *&c.*

1. This is a ſhrub, with four-cornered, rugged branches. Leaves oppoſite, petioled, ovate, oblong, quite entire, longer than the branch-joints, rugged on both ſides. Pedunicles axillary, oppoſite, ſolitary, four-cornered, ſhorter by half than the leaf, two-leaved at top with three-flowered pedicels. Partial involucre four-leaved? Leaflets obovate, the length of the calyxes, blunt, containing three ſeſſile florets[1]. Corolla funnel-ſhaped, with a ſix or eight-cleft border. Capſule coriaceous, ſuperior, obcordate or obovate, turgidly lenticular, in the twin middle ventricote and marked with a longitudinal elevated ſtreak, compreſſed at the ſides into a narrow ſharp margin, the reſt brittle, two-celled, bipartile; with the ſegments plano-convex, of a brown chefnut colour on the outſide, pale within, quite entire, valveleſs. Receptacle none; ſeed faſtened to the bottom of the cell, obovate, moderately acuminate downwards, convex on one ſide, flat on the other, brown. Nyctanthes (Jaſminum Sambac) has a fleſhy berry, and the ſeeds incloſed within an elaſtic aril, like Coffee; hence differing greatly from this[2], and joined in our work with Jaſminum.

Native of the Eaſt Indies. Introduced in 1781, by Sir Joſeph Banks[3].

The other ſpecies ſhould have been united to Jaſminum, but having been omitted under that genus, are given here rather than omit them entirely.

2. This is a ſhrub, attaining the height of a man. The young ſhoots are hairy. Leaves ſhining green, ſmooth, even, in pairs from the joints, bitter, without any ſmell. Flowers white, three or five together. Calycine ſegments about ſix; of the corolla ſix, ſeven or eight, narrow, very much waved on the edge outwardly. Fruit ſuperior, ſmooth and black like a ſmall cherry, with a thin ſkin, and a ſoft, dark-red, ſweetiſh pulp, containing a round hairy ſeed.

Native of the Eaſt Indies, where it is much cultivated on account of the ſweetneſs of the flowers, which the women there wear in their hair[4].

3. This is a tall tree, with a thick trunk of a chalk white wood, covered with a dark purple, ſmooth, inodorous, inſipid bark. Leaves oppoſite, decuſſated, acuminate, ſoft, ſmooth, ſhining, dark green above, on round, rufous, lanuginous petioles. Flowers on the more tender branches, on long, rufous, lanuginous pedunicles, from the axils of the leaves, three, four or more together, white, ſmelling very ſweet, opening during the night, and fading at ſun-riſe[5].

Leaves elliptic-lanceolate or ovate, waved. Calyx cylindrical, ſix-cleft; ſegments equal. Segments of the corolla eight, oblong, pointed, ſhorter than the tube. Filaments ſhort. Anthers oblong, and longer than the filaments[6].

Native of the Eaſt Indies and China.

4. Rheede compares this with Jaſminum Sambac, and ſays that the twigs are of a more duſky green approaching to brown; the leaves ſometimes more oblong, yet without any point, ſometimes wider, oppoſite, petioled, of a more duſky green than any of the reſt, and of a bitter taſte[7]. Calycine ſegments ſix; corolline from ſix to ten or eleven, lengthened out into a ſort of prickle at the end, very narrow and white, except at the edge where they are tinged with red. The ſmell is very fine.

Native of Malabar, in a ſandy ſoil; at about Crangannor, Caroer, &c. flowering in June and July[8].

5. Branches round, the upper ones villoſe. Leaves ſmooth; the lower ones cordate, ovate. Flowers terminating, five or ſix, in a ſort of umbel. Calyx very ſmall, with the ſegments awl-ſhaped, and hairy. Tube of the corolla thickened above.—Native of the Eaſt Indies[9].

6. This is a ſhrub with weak, ſmooth branches, like oſiers. Leaves on ſhort petioles, naked, an inch long. Pedunicles ſhort, ſolitary. Calyx truncated, with awl-ſhaped teeth ſhorter than the tube of the corolla, which thickens gradually; ſegments the length of the tube, linear-lanceolate. Koenig ſent it from Tranquebar[10].

Retzius thinks that this may poſſibly be the ſame with N. grandiflora of Loureiro, which he thus deſcribes—Stem ſhrubby, erect, five feet high, thick, rugged. Leaves ſtellate by threes and oppoſite, ovate, ſubcordate, ſubacute, wrinkled, ſmooth. Flowers white, double, terminating, one or two together, three times as large as thoſe of the Sambac, handſomer, but inferior in fragrance. Calyx ten-cleft, with linear, erect ſegments. The loweſt order of ſegments in the corolla inconſtant in number. Cultivated both in China and Cochinchina.

7. This alſo is a ſhrub with oppoſite white-haired branches. Leaves oppoſite, petioled, quite entire; the uppermoſt roundiſh. Flowers in bundles, at the ends of the branches. Bractes lanceolate, hirſute. Calyx hirſute, with long, linear teeth. Corolla one of the largeſt of the genus, ſmooth, with a tube longer than the teeth of the calyx. Sent from Calcutta by Koenig[11].

PROPAGATION AND CULTURE.

See Jaſminum Sambac.] They require the ſame treatment with that, but are more difficult to propagate.

DESCRIPTIONS, *&c.*

Theſe are herbaceous perennial plants, with long tuberous roots. Leaves alternate, on a very long petiole, half theathing below, floating. Pedunicles long, naked like ſcapes, one-flowered. Flowers large, emerging. Germ and ſtigma approaching to the Poppy[1].

1. Petioles half round, commonly erected above the water. Leaves cordate-oblong, more narrowed towards the top than in N. lutea. Peduncle round. Leaflets of the calyx roundiſh, blunt, concave: the three outer ſpreading, green on the outſide, dirty purple within, an inch in diameter: the three inner twice as large, ſuberect, yellow on the outſide, within dirty purple. Petals about thirteen, inſerted into the ſides of the receptacle in a ſingle row, ſomewhat wedge-ſhaped, bluntly rounded, from ſpreading reflex, yellow, three lines wide. Filaments very numerous, inſerted in ſeveral rows into the receptacle, linear, a line in width, ſcarcely half an inch in length, firſt erect then reflex, yellow, red in the middle. Anthers linear, two on each filament, faſtened to the edges of it. Germ columnar, deeply grooved, with thirteen angles, yellow. Stigma peltate, ſlightly umbilicate, yellow, with thirteen rays, deeply toothed at the edge with thirteen blunt teeth, green above.

Native of North America. Introduced in 1772. by Mr. William Young. It flowers in July[2].

2. The leaves of the Yellow Water Lily are ſmooth, plane, except that they turn up a little at the edge to keep off the water, tough and pliant, ten or twelve inches in diameter, floating, ovate or nearly orbicular, bright green above, paler underneath, with branched raiſed nerves or veins. Petioles ſmooth, three-ſided, their length depending on the depth of water: I have one before me on the 8th of june 1768, five feet and a half in length. The caſe is the ſame with the peduncle, which always elevates the flower above the water; but after it is impregnated, the ſeeds are ripened under water, and fall into the mud at bottom to produce new plants. The peduncles are round, ſucculent and one-flowered. Flowers an inch and half

[1] Juſſieu. [2] Hort. kew.

in

in diameter, having a vinous ſmell. Calyx larger than the corolla: leaflets roundiſh, blunt, erect, quite entire, ſubſinuate, ſmooth, tough, yellow, except at the baſe on the outſide, where they are green, inſerted into the baſe of the germ, regular, almoſt an inch in length and breadth. Petals fleſhy, yellow, about half an inch in length and five lines in breadth, notched and grooved, from ten to twenty in number. Stamens very numerous, one hundred or even one hundred and ſixty-five in number, when the flower firſt opens preſſing cloſely on the germ, but after they have ſhed their pollen bending back: filaments yelloviſh, thicker than the anthers, ſeparate from the germ: anthers yellow, two lines in length. Germ ovate, blunt, ſmooth, terminated by a hollow in form of a navel. Style thick and very ſhort, or ſcarcely any. Stigma yellow, unequally and ſometimes obſcurely notched, a little convex, having eleven or twelve rays, and being depreſſed at the centre[*]. The fruit is ſhaped like a bottle, or ovate-conical, very ſmooth, crowned with the ſtigma, which is grooved, quite entire and peltate: within it is divided into from twelve to fifteen cells; which are irregular, ſubdivided by partial partitions, ſo that each ſeed has as it were its own cell. Seeds fewer than in N. alba, but twice as large, ovate-acuminate, yelloviſh, very ſmooth and ſhining, keeled with an angle. Embryo lenticular-conical, glued to the hole of the albumen, and covered only by the integuments of the ſeed[*].

Linnæus tells us that ſwine are fond both of the leaves and root, that goats are not fond of it; and that kine, ſheep and horſes refuſe it: alſo that crickets are driven out of houſes by the ſmoke in burning it, and that both they and cock-roaches are deſtroyed by the roots rubbed or bruiſed with milk. Ray obſerves, that the flowers ſmell like brandy. Dr. Withering informs us, that an infuſion of a pound of the freſh root, in a gallon of water, taken in the doſe of a pint night and morning, cured a leprous eruption of the arm.

Yellow Water Lily is native of moſt parts of Europe, in ſlow rivers, pools and ditches, flowering in July and auguſt.

Kalm obſerved the ſame ſpecies in Canada, with a flower ſcarcely ſo big as that of Caltha paluſtris.

In German it has the various names of *die gelbe Seeblume, gelbe Seeroſe, gelbe Plompen, gelbe Mummela, gelbe Waſſerblume, gelbe Seekandel, gelbe Weiberroſen, gelbe Waſſerlilie, Kannenplompen, Nixblumen, Hoarwurz, Hoarſtrang, Poppeike.* In Dutch, *Geele plompen.* In Daniſh, *Aakandel, Seeblomſter, Haarred.* In Swediſh, *Nixblad.* In Smoland, *Siollon.* In Scania, *Akanna.* In French, *le Nenuphar jaune.* In Italian, *Nenufaro giallo, Ninfea gialla.* In Spaniſh, *Nenufar amarilla, Eſcudete.* In Portugueſe, *Nymphea amarella, Golfao.*

3. Root tuberous, frequently the ſize of the human arm, creeping far and wide and deep in mud. The whole plant is larger in all its parts than the preceding. The leaves are much the ſame, only larger. Petioles and peduncles round, within full of pores, four of which are generally larger than the reſt; hairs interwoven between. Flowers large, being ſometimes ſix inches in diameter, very handſome and double. Calycine leaflets ſmaller than the outer petals, being about two inches long, and an inch wide, ovate, blunt, ſpreading, ſmooth and yelloviſh green on the outſide with a white edge, ſtriated and ſhining, within white. Petals white, from ſixteen to twenty or twenty-four in number, in two or three rows, wider than the leaves of the calyx, and more ovate; the outer ones have a green ſtreak along the back, and approach more to the nature of the calyx; as the inner ones, which are gradually ſmaller, do to the ſtamens: they are inſerted at the baſe of the germ. Stamens ſixty-eight or ſeventy, ſometimes as many as eighty-ſix; filaments ſhort, thick, wide, ovate-lanceolate, faſtened to the ſide of the germ, white; the inner ones yellow, bent inwards, the outermoſt reſembling the inner petals. Germ roundiſh. Style none. Stigma rayed, having little reflex notches about the edge, ten lines in diameter; each ray correſponding to a cell in the germ[*]. Berry ſuperior, ſpherical, warted with the remains of the filaments, umbilicated with a very large, concave, grooved, crenulate ſtigma, like the Poppy, and having twenty cells or thereabouts: rind thin, leathery: pulp of the cells gelatinous, drying up to a ſpongy ſubſtance. Seeds very numerous, oblong-ſpheroidal, ſmooth, ſhining, having a very blunt angle on one ſide, yelloviſh green or livid, naſtling in the pulp, without any certain ſituation or order. Albumen both in this and the preceding of the ſame ſhape with the ſeed, farinaceous, very white, friable, with an open hole at the baſe, embryo in this monocotyledonous, lenticular-globular, fleſhy, yelloviſh, ſlightly immerſed in the cavity of the albumen, not covered by the ſubſtance of it, but only by the common integuments of the ſeed[*].

According to Linnæus, the flower raiſes itſelf out of the water and expands about ſeven o'clock in the morning, and cloſes again, repoſing upon the ſurface, about four in the evening.

The roots have an aſtringent bitter taſte; they are uſed in Ireland, in the highlands of Scotland, in the iſland of Jura, &c. to dye a dark brown or cheſtnut colour. Swine are ſaid to eat it, goats not to be fond of it, kine and horſes to refuſe it. The flowers, the herb and the root were formerly uſed in medicine, but are all now obſolete.

White Water Lily or Water Roſe, is native of moſt parts of Europe, in ſlow ſtreams, pools and ditches, flowering in July and auguſt. Both this and the preceding are called in ſome counties *Water-can* or *Candock*, and *Wuterſocks*. In German it is *die weiſſe Seeblume* or *Seeroſe, Waſſerlilye, Waſſerambren, Waſſernanacken, weiſſe Waſſerblumen, Waſſerroſe, Waſſerachn, Waſſerlilie, weiſſe Weiberroſe, weiſſe Seekandel, Seepappen, weiſſe Seeplompen, weiſſe Plumpen, weiſſe Mummele, Haarwurz, Haarſtrang, Tell-lilie, Kellerwurz, Kellerwurz, Kehlwurz, Kohlwurz, Kenkwurz, Herkuleswurz, Harzwurz, Murmelken.* In Dutch, *Witte Plompen, Pauneknock, Meirkland, Waterroos.* In Daniſh, *Aakande, Seeblomſter, Seeblommer, Seeblad, Hazred, Kierringekrus, Fruar, Kiodneblom.* In Swediſh, *Sjoblad.* In French, *le Nenuphar blanc, Lis d'etang.* In Italian, *Nenufaro bianco, Ninfea bianca.* In Spaniſh, *Nenufar blanco, Ninfea blanca, Eſcudete, Higo de rio.* In Portugueſe, *Nymphea branco, Golfam, Golfao.* In Ruſſian, *Wodanoi lelei, Kuliſchka.*

4. This is altogether different from the ſmaller variety of the preceding ſpecies, which differs from the common White Water Lily in nothing but in ſize. It is a native of North America and the Eaſt of Siberia; was introduced in 1786 by William Hamilton Eſq., and flowers in july[*].

5. Egyptian Water Lily reſembles our common White ſpecies very much in the form of the flower and leaves, but the latter are toothed about the edge. It is native of the hot parts of the Eaſt Indies, Africa and America. It is very common in ponds, lakes and rivers in Jamaica: and grows in vaſt quantities in the plains of Lower Egypt near Cairo, during the time they are under water. It flowers there about the middle of ſeptember, and ripens towards the end of octobers. The Arabians call it Nuphar. The ancient Egyptians made a bread of the ſeed of the Lotus dried and ground.

6. Root horizontal, long, creeping, conſiſting of joints linked together, ovate-oblong, white, fleſhy, eſculent, tubular within. Leaves exactly peltate, with a cavity in the centre above, and dichotomous veins ſpringing from the ſame centre, orbiculate with a point on each ſide, a little waved, thin, paler underneath, ſmooth, of different ſizes from four to twelve inches. Petioles erect, very ſtraight, round, hiſpid or muricated, thicker below, attenuated above. Pedunicle the thickneſs of a finger below, attenuated above, ſpongy, muricated, one-flowered. Flower as large as the palm of the hand, or larger, purple. Calyx four-

[*] Pollich. Knoch. Gunner. Villars. Lightf. Withering.
[*] Gærtner.

[*] Pollich. Villars. Lightf. Relhan. [*] Gærtner.
[*] Hort. Kew.

leaved: leaflets concave, ſpreading, deciduous. Corolla conſiſts of fifteen petals or more, ovate, ſubacute, concave, many-nerved on the outſide, ſpreading. Stamens ſixty or more, ſhorter than the corolla: anthers linear, white, very long, placed on the receptacle. Germ retundate, ſuperior. Styles as many as there are ſeeds, thick and very ſhort: the ſtigmas thicker. Pericarp turbinate, truncate, grooved, corticoſe, opening at top, cells one-ſeeded, as far as thirty. Seeds ovate, half an inch long, white, hardiſh, eatable, with a thin, ſmooth, black rind[a].

What is commonly named the pericarp, Gærtner calls the Common Receptacle, and deſcribes it as inverſely conical, ſuberous or fungous, flat above, having round, ſeparate cells within, equal in number to the ſeeds. The proper receptacle is a very ſhort umbilical chord reaching from the bottom of the cell to the baſe of the ſeed, and inſerted into the umbilical cavity. Seeds nucamentaceous, from fifteen to thirty, oblong-ſpheroidal or nearly globular, with the ſhort permanent ſtyle at top, and a very minute umbilical pore at the baſe, ſmooth, blackiſh, or of a reddiſh brown colour. The receptacle in ſome is ſharply, in others parabolically conical, in others almoſt hemiſpherical, in others again very much flatted. It varies alſo in conſiſtence; being either fungoſe, ſo that it may be eaſily compreſſed by the fingers, or ſuberoſe, or elſe cruſtaceous and hard. Finally, it differs in the number of cells from twelve to thirty.

The Nelumbo is the connecting link between the monocotyledonous and dicotyledonous plants; for by the ſtructure of the ſeed it appears to belong to the latter, but in reality it ranks with the former, for it conſtantly puts forth one leaf only in germination, and does not produce a ſecond, till the firſt is entirely unfolded above water: this Gærtner ſays he has found to be the caſe in more than fifty nuts that were ſent him by Lerche.

β. Differs in having hard ſeeds; in other circumſtances it agrees with the other ſo much as ſcarcely to be diſtinguiſhed.

Nelumbo or peltated Water Lily is a native both of the Eaſt and Weſt Indies, China, Cochinchina and Japan, Perſia and ſome parts of the Ruſſian Empire. Browne ſays it is pretty common in the lagoons beyond the ferry in Jamaica, but not in the deeper waters. Thunberg informs us, that it is conſidered as a ſacred plant in Japan, and pleaſing to their deities, and that the images of their idols were often ſeen ſitting on its large leaves. The long ſtalks are eaten among other pot-herbs. It differs from the Egyptian Lotus in having entire thin leaves, with the petiole and peduncle rugged.

Loureiro relates that it abounds in muddy marſhes, and is cultivated in large handſome pots in the gardens and houſes of the mandarines; that there is a variety with the flower of a pure white, and another with a very beautiful luxuriant flower, having about one hundred large petals, white or roſe-coloured. Both root and ſeeds are eſculent, vapid and wholeſome. They are accounted cooling and ſtrengthening, and to be of ſervice in extreme thirſt, diarrhœa, tenеſmus, vomiting, and too great internal heat.

In China it is called *Lien-whoa*, and the ſeeds and ſlices of the hairy root, with the kernels of apricots and walnuts, and alternate layers of ice were frequently preſented to the Britiſh ambaſſador and his ſuite at breakfaſts, given by ſome of the principal mandarines.

The Chineſe have always held this plant in ſuch high value, that at length they regarded it as ſacred. That character however has not limited it to merely ornamental purpoſes; for the roots are not only ſerved up in ſummer with ice, but they are alſo laid up in ſalt and vinegar for the winter. The ſeeds are ſomewhat of the ſize and form of an acorn, and of a taſte more delicate than that of almonds. The ponds are generally covered with it, and exhibit a very beautiful appearance, when it is in flower: and the flowers are no leſs fragrant than handſome.

Sir George Staunton remarks that the leaf, beſides its common uſes, has from its ſtructure, growing entirely round the ſtalk, the advantage of defending the flower and fruit, growing from its centre, from any contact with the water, which might injure them. He alſo remarks that the ſtem never fails to aſcend in the water from whatever depth, unleſs in caſe of a ſudden inundation, until it attains the ſurface, where its leaf expands, reſts and ſwims upon it, and ſometimes riſes above it. But this property it has in common with the other ſpecies of Nymphæa. This plant bears the rigorous cold of the Pekin winter, though it is reared with difficulty in European ſtoves. It often grows ſpontaneouſly in China, and is propagated in the open air with eaſe, both by the ſeed and root. The Chineſe diſtinguiſh many varieties of it.

From the root of the Nelumbo, Sir George Staunton ſays, the Egyptians are ſuppoſed to have prepared their Colocaſia, but the plant is now no longer found in that country: from which circumſtance ſome naturaliſts infer, that it never was indigenous there; but cultivated by the inhabitants with extreme care. The ancient Romans made repeated efforts to raiſe it among them, from ſeeds brought out of Egypt; and the modern attempts to cultivate it in Europe, though with the aſſiſtance of artificial heat, ſeldom have ſucceeded[f].

Dr. Patrick Browne is of opinion that the ancients confounded two plants under the name of Lotus or Egyptian Bean, and that under theſe titles they deſcribed the upper parts of the Nymphæa Nelumbo, and the roots of the leſſer Colocaſia, now commonly called Coccos in Jamaica. *Arum Colocaſia*[g].

The tree Lotus muſt not be confounded with the Nymphæa. Mr. Mungo Park, in his late extenſive peregrinations in Africa, diſcovered it to abound in all the countries he traverſed, but flouriſhing moſt in a ſandy ſoil. It is rather a thorny ſhrub than a tree. The fruit is a ſmall farinaceous berry, which being pounded and dried in the ſun, is made into excellent cakes, reſembling in colour and flavour the ſweeteſt gingerbread. A liquor alſo is prepared from it, deliciouſly ſweet; the ſame perhaps which is fabled to have produced ſuch extraordinary effects on the companions of Ulyſſes[h].

" The trees around them all their food produce,
" Lotos the name, divine, nectareous juice!
" Thence call'd Lotophagi, which whoſo taſtes,
" Inſatiate riots in the ſweet repaſts,
" Nor other home, nor other care intends,
" But quits his houſe, his country, and his friends!."

Theophraſtus deſcribes the Lotus tree as ſomething leſs than the pear-tree, with leaves cut about the edges, and reſembling thoſe of the Ilex or ever-green oak. He adds, that there are ſeveral ſorts or varieties, differing in their fruit, which is the ſize of a bean, and grows thick upon the branches like myrtle berries. The poets repreſent the Lotus as an aquatic tree. Ovid calls it *aquatica Lotus*. Martial ſays:

" Nec plus Lotos aquas, littora myrtus amat."

And Virgil joins it with the Willow. Mr. Park ſays it affects a ſandy ſoil, but he does not inform us whether it is found near water. See Lotus.

Nymphæa Nelumbo was introduced here in 1787, by Sir Joſeph Banks[k].]

PROPAGATION AND CULTURE.

2. 3. The beſt method to propagate theſe plants is, to procure ſome of their ſeed veſſels juſt as they are ripe and ready to open, and to throw them into canals or large ditches of ſtanding water, where the ſeeds will ſink to the bottom, and the following ſpring the plants will appear floating upon the ſurface of the water. When they are once fixed to the place, they will multiply exceedingly, ſo as to cover the whole ſurface of the water in a few years.

They may alſo be cultivated in large troughs or ciſterns of water, having earth at the bottom, and will flouriſh very well in them, annually producing great quantities of flowers.

DESCRIPTIONS, *&c.*

1. The upland Tupelo-Tree or Sour Gum grows naturally in Pennſylvania and perhaps elſewhere, riſing with a ſtrong upright trunk to the height of thirty or forty feet, and ſometimes near two feet in diameter; ſending off many horizontal, and often depending branches. Leaves obovate, a little pointed, entire, of a dark green and ſhining upper ſurface, but lighter and a little hairy underneath: thoſe of male trees are often narrower and ſometimes lance-ſhaped. The flowers are produced upon pretty long common footſtalks, ariſing from the baſe of the young ſhoots, and dividing irregularly into ſeveral parts, generally from ſix to ten; each ſupporting a ſmall flower, having a calyx of ſix or ſeven unequal leaves, and from ſix to eight awl-ſhaped ſpreading ſtamens, ſupporting ſhort four-lobed anthers. The female trees have fewer flowers produced upon much longer ſimple cylindrical footſtalks, thickened at the extremity, and ſupporting generally three flowers, ſitting cloſe and having a ſmall involucre. They are compoſed of five ſmall oval leaves, and in the centre an awl-ſhaped incurved ſtyle, ariſing from the oblong germ, which is inferior, and becomes an oval oblong berry, of a dark purpliſh colour when ripe. The timber of this tree is cloſe grained and curled ſo as not to be ſplit or parted; and therefore much uſed for hubs of wheels of carriages, &c.[1]

It was cultivated in 1750, by Archibald Duke of Argyle[2].

Mr. Miller has the Nyſſa aquatica, probably this ſpecies, in the two quarto editions of his Dictionary, 1763, and 1771 but not in the two folio editions of 1759 and 1768. His deſcription is very imperfect.]

[1] Marſhall. [2] Hort. kew.

He ſays that it grows naturally in Virginia and ſeveral other parts of North America, and that it had been introduced of late years into the Engliſh gardens, but had made little progreſs.

[2. The Virginian Water Tupelo-Tree grows naturally in wet ſwamps, or near large rivers in Carolina and Florida; and riſes with a ſtrong upright trunk to the height of eighty or an hundred feet, dividing into many branches towards the top. The leaves are pretty large, of an oval-ſpear-ſhaped form, generally entire, but ſometimes ſomewhat toothed, and covered underneath with a whitiſh down: they are joined to long ſlender footſtalks, and affixed to the branches in ſomewhat of a verticillate order, preſenting a beautiful varied foliage. The berries are near the ſize and ſhape of ſmall olives, and are preſerved as that fruit is by the French inhabitants upon the Miſſiſippi, where it greatly abounds, and is called the Olive tree. The timber is white and ſoft when unſeaſoned, but light and compact when dry, which renders it very proper for making trays, bowls, &c.[1]

It was introduced here in 1735, by Peter Collinſon, Eſq.[2]

Mr. Humphrey Marſhall, in his American Grove, quoted above, adds a third ſort, from Bartram's catalogue, which he calls Nyſſa Ogeeche, or Ogeeche Lime-tree. He deſcribes it as a tree of great ſingularity and beauty, growing naturally in water, in the ſouthern ſtates, and riſing to the height of about thirty feet. The leaves are oblong, of a deep ſhining green on their upper ſides, and lightly hoary underneath. The flowers are male and female upon different trees, and are produced upon divided, or many-flowered footſtalks. The fruit is nearly oval, of a deep red colour, the ſize of a Damaſcene Plum, and of an agreeable acid taſte, from which it is called the Lime-tree.

Mr. Bartram informs us that he ſaw large tall trees of this ſort on the banks of the Alatamaha river, growing in the water, near the ſhore. He calls it Nyſſa coccinea; and obſerves that there is no tree which exhibits a more deſirable appearance than this, in the autumn, when the fruit is ripe, and the tree diveſted of its leaves: for then they look as red as ſcarlet, with their fruit, which is of that colour alſo. It is the ſhape of the Olive, but larger, and contains an agreeable acid juice. The leaves are oblong lanceolate and entire, ſomewhat hoary underneath; their upper ſurface of a full green and ſhining; the petioles ſhort. The peduncles are many-flowered. The moſt northern ſettlement of this tree yet known, is on Great Ogeeche, where it is called Ogeeche Lime, from the acid fruit being about the ſize of Limes, and being ſometimes uſed in their ſtead[3].]

PROPAGATION AND CULTURE.

Theſe trees may be propagated by ſeeds, procured from places where they grow naturally, and put into the ground as ſoon as they arrive, for they always lie a year before they come up. Sow them in pots filled with light loamy earth, placing them where they may have only the morning ſun; during the firſt ſummer the pots muſt be kept clean from weeds, and in dry weather duly watered. In autumn plunge the pots into the ground, and if the winter ſhould prove ſevere, cover them with old tan, peas-haulm, or other light covering. The following ſpring plunge them into a moderate hot-bed, hooped over and covered with mats; obſerving conſtantly to keep the earth moiſt. This will bring up the plants by the beginning of may. They muſt be gradually hardened to bear the open air: during the following ſummer plunge the pots again into an eaſt border, and duly water them in dry weather. In autumn remove them into a frame, where they may be ſcreened from froſt; but in mild weather expoſed to the open air. The ſpring following, before the plants begin to ſhoot, part them carefully, and plant each in a ſmall pot filled with loamy earth, and if they are plunged into a moderate hot-bed, it will forward their putting out new roots: then

[1] Marſhall. [2] Hort. kew. [3] Travels, p. 17.

they may be plunged in an eaſt border, and in winter ſheltered again under a frame. The ſpring following, ſuch plants as have made the greateſt progreſs, may be planted in a loamy ſoil, in a ſheltered ſituation, where they will endure the cold of this climate, but unleſs the ground is moiſt they make very little progreſs.

DESCRIPTIONS, *&c.*

Theſe are ſmall trees, with alternate ſtipulaceous leaves, and the flowers in terminating ſpikes or panicles. Commerſon has mentioned two ſpecies, natives of Madagaſcar, under the name of *Sophiſtoques*, one many-ſtamened with long permanent filaments and ſhort anthers, ten-fruited, with the heart of the ſeeds ſtraight, the other ten-ſtamened with long erect ſubſeſſile caducous anthers and five-fruited; both one-ſtyled and reſembling this genus[a].

1. This is a ſmall tree. Leaves alternate, oblong, acute, finely ſerrate, ſmooth, on ſhort petioles, the youngeſt remarkably coloured with purple, four or five inches long and two broad. Panicles faſcicle-like, from the naked branchlets, below the young leaves. Bractes ſmall, falling. Flowers large, yellow, inodorous. Calyx five-leaved: leaflets oblong, as large as the petals, but not coloured, permanent. Petals from ſeven to twelve, generally nine or ten, oblong, falling. Filaments ſhort, permanent. Anthers linear, erect, falling. Germs generally as many as there are petals, ſurrounding a half round receptacle. Style from the apex of the receptacle, rather longer than the ſtamens, permanent. Stigma perforated. Pericarp none. Receptacle half-round, coloured with a ridge for each ſeed or petal, that was in the corolla: on each ſits an oblong ovate ſeed, as in Quaſſia, about the ſize of a large kidney-bean, ſmooth, when ripe black. All the ſeeds rarely come to perfection[b].

Linnæus remarks, that the Eaſt Indian plant is certainly the ſame with Plukenet's, though the leaves of this are more ovate, and thoſe of the former ovate-lanceolate, very finely and acutely ſerrate. He alſo remarks a ſingularity in this plant, whence it derives the trivial name, that the racemes periſh below the leaves, whence the branchlets become very ſquarroſe, after the flowers and pedunckes are fallen. In his ſpecimen the petals had fallen off, and in Schreber's edition of the genera it is deſcribed as having no corolla.

Native of the Eaſt Indies and Africa. In the Circar mountains, it flowers about the beginning of the hot ſeaſon, at which time the leaves begin to come out, having caſt them during the cold ſeaſon[c].

In Ceylon it is called *Bukeeware*, and it is the *Yerra-jurvie* of the Tellingas.

[a] Juſſ. gen. [b] Roxburgh. [c] Idem.

2. This is a middle-sized tree, with a gray irregular bark, and a soft pliant wood. Leaves alternately oppofite, pale green. Flowers abundant on certain branchlets, yellow and very sweet[1].

Swartz, who joins it with his *nitida* (our Gomphia nitida), and places it in the class Decandria, obferves that the petals are three times as large as the calyx, and that the fruit is a drupe immerfed in the receptacle. In the generic character it is not confidered as a pericarp but a receptacle. Gærtner thus defcribes the fruit: — Berries one, two, or three, feldom more, rounded or ovate-globular, fubcoriaceous, thin, fmooth, black or red, one-celled. Common receptacle fleshy from the receptacle of the flower enlarged; fometimes fimply globular, fometimes having two or three rifings, according to the number of the berries: proper receptacle none. Seeds folitary, fubglobular, the fize of the cavity in the berry, pale, faftened to the bafe of the common receptacle.

Pifo fays, that on each pedicel of the raceme there is a berry, the fize of a cherry-ftone, triangular-conical, and that three or four oval, feffile berries are joined to thefe, of the fame fize, all black, like thofe of our Vaccinium Myrtillus or Whorts, of an aftringent tafte; and that they are not only eaten crude, but that an oil is expreffed from them, which is ufed in falads.

Native of South America.

3. This is a fhrub refembling O. fquarrofa except in the fize of the leaves and inflorefcence. Branches round, fmooth, with an afh-coloured dotted bark. Leaves only on the branchlets, petioled, oblong, ferrulate, quite entire at the bafe, veined, fhining, half an inch in length. Peduncles at the fides of the branchlets, folitary, gradually thickening upwards, purple, longer than the leaf[2].

Ochna. See *Gomphia*.

Huampo Americanorum.

DESCRIPTION, *&c.*

This is a very large tree, with divaricating branches. Wood white, tender, and fo light that it is ufed inſtead of cork to nets. Bark thick, fibrous, afh-coloured, varied with white fpots, and netted with rufeſcent wrinkles. Leaves more than a foot, fometimes above a foot and half in diameter, angular, on long petioles, above fmooth and dark green, underneath pale with rufeſcent hairs. Stipules ovate-lanceolate, ferruginous, deciduous. Flowers on the upper branchlets, on thick ſtraight peduncles. Calyx greenifh red, with the fegments or rather notches rounded, partly white, partly greenifh red. Petals white, fleſhy, reflex and convoluted. Capſule eight or ten inches long. Seeds very fmall, fmooth, fubovate, involved in a very ſoft fine ruſtous down[3].

Native of America, frequent in the Antilles. Browne fays it abounds on the Banks of Spaniſh Town River, in Jamaica. Deſportes, in his Plantes utiles de S. Domingue, vol. 3. p. 16, 17. fays that the beauty of the Engliſh Beavors is chiefly to be aſcribed to the down in the fruit of this tree.

OCHROXYLUM (ωχρος ξυλον: *pale wood.*)

Lin. gen. Schreb. n. 508. (Curtiſia.) *p.* 826. (Ochroxylum.)

Claſſ. 5. 3. Pentandria Trigynia.

GENERIC CHARACTER.

Cal. *Perianth* five-cleft, very ſmall, permanent: *ſegments* ovate, acute, ſpreading a little.

Cor. *Petals* five, ovate, reflex, bluntiſh, excavated below the tip, thickiſh with a thinner margin.

Nectary an annular gland, ſubtrilobate, fleſhy.

Stam. *Filaments* five, awl-ſhaped, flattiſh below, erect, a little longer than the coroſla. *Anthers* roundiſh, incumbent.

Pist. *Germs* three, placed on the nectary, outwardly gibbous. *Styles* ſhort. *Stigmas* ſimple.

Per. *Capſules?* three, approximating, ſubglobular, inwardly compreſſed, placed on the lobes of the nectary, now become larger and three-lobed, one-celled, opening on the inſide?

Seeds two, convex on one ſide, compreſſed and angular on the other.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Pet. five. Nect.* an annular three-lobed gland. *Capſ.?* three, approximating, one-celled, two-feeded.]

Ochrus. See *Piſum.*

OCIMUM (*of Pliny:* ωκιμον *of Hippocrates, Theophraſtus and Dioſcorides:* ωκυον, *cito* (germinans). *So named from its being ſuppoſed to germinate haſtily.—Others derive it* απο του οζειν, *from its ſtrong ſmell. Some diſtinguiſh* Ocymum *from* Ocimum; *making the former a plant ſown for fodder, the latter an herb remarkable for its ſweet ſmell.*)

Lin. gen. n. 732. *Reich. n.* 790. *Schreb. n.* 986. *Tournef. t.* 96. *Juſſ.* 116.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ. Labiatæ*, Juſſ.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, two-lipped, very ſhort, permanent: *upper lip* flat, orbiculate, wider, ascending: *lower lip* four-cleft, acute, converging.

Cor. one-petalled, ringent, refupine: *tube* very ſhort, ſpreading; *one lip* turned upwards, wider, half-four-cleft, blunt, equal: *the other lip* turned downwards, narrower, entire, ſerrate, longer.

Stam. *Filaments* four, declined; two a little longer, and two putting forth a reflex proceſs at the baſe. *Anthers* half-mooned.

Pist. *Germ* four-parted. *Style* filiform, ſituation and length of the ſtamens. *Stigma* bifid.

Per. none. *Calyx* cloſed, cheriſhing the ſeeds.

Seeds four, ovate.

Obs. *The flexure of the ſtamens ſhows that it is the upper lip of the petal, which is turned downwards, and the lower which is turned upwards. The eſſential character conſiſts in the reflex proceſs of the two filaments.*

ESSENTIAL CHARACTER.

Cal. with the upper lip, orbiculate, the lower four-cleft. *Cor.* refupine, with one lip four-cleft, the other undivided. *Filam.* the two outer putting forth a reflex proceſs at the baſe.

Racemes whorled red-like, leaves oblong serrate.

DESCRIPTIONS, &c.

These are either herbs or undershrubs, having a strong sweet smell. Their flowers are in whorls forming a loose spike, terminating and axillary. They have square stalks and opposite leaves, as common with the other verticillate plants: and are distinguished by having the corolla turned upside-down, and a process at the base of the two shorter filaments[a].

1. Stem erect, woody, a foot and half high, the whole subdivided into branches, brachiate or panicled with round branchlets, channelled on both sides. Leaves petioled, elliptic-lanceolate, green on both sides, naked, slightly serrate, quite entire at the base, scarcely rugged at the keel, acuminate. Panicles of the branches terminating, brachiate, close or cluttered, scarcely longer than the leaves, from whorled purple branches. Bractes lanceolate, purple, with the upper lip ovate. Corollas purple, pale on the outside, with the lower lip white. Stament white. Pistils purple. It differs from the rest in being more branched like a shrub, in the leaves being green and more lasting, with the smell of Rue, and the flowers fascicled in a thyrse.

Native of the East Indies[b].

2. Stem erect, a foot high, roundish, somewhat hairy, with the branches commonly superaxillary. Leaves petioled, ovate, blunnish, naked, serrate, scarcely ciliate. Racemes with six-flowered whorls. Upper lip of the calyx heart-shaped, with three streaks. Bractes heart-shaped, caducous. Corollas smaller, white with the lower lip purple. Filaments purple, the length of the corolla, without teeth at their base, but instead of them the alternate ones are villose at the base. This is an annual plant, but its native place is unknown[c].

3. Stem suffruticose, hard and perennial at the base, stiff and straight. Leaves with the rib hoary-tomentose above. Spikes before flowering four-cornered,

[a] Juss. gen. [b] Linn. mant. [c] Idem.

with

with subulate-prominent bractes. Bractes cordate, acute. Flowers small. Corollas white with yellow anthers [1].

According to Loureiro it is cultivated in Cochinchina for the kitchen; the ſtem is five feet high, four-grooved, ſmooth, white and branched. Leaves ſubſerrate, dotted underneath, lanuginoſe above, pale, ſmelling very ſtrong, petioled. Corolla white with coloured calyxes, in ſpiked racemes lateral and terminating.

Native of the Eaſt Indies. Cultivated in 1752, by Mr. Miller [2].

4. Stem a foot high, greeniſh white, woody at the baſe. Racemes few. Leaves broader and thicker than in the other ſorts, concave, bluntly ſerrate. Bractes lanceolate, cordate or ovate, acute, before the flowers come out longer than the flower, and forming a quadrangular ſpike. Corollas large, white, crenate, with the upper lip four-cleft, but the lateral ſegments more divaricating. Filaments white.

It is an annual plant, native of the Eaſt Indies, and the iſland of Java [3].

5. Stem a foot high, the whole even, ſhorter than the raceme, aſcending. Oppoſitions of the leaves five or ſix, even, with two ſerratures on each ſide, on petioles of the ſame length with themſelves. Raceme erect, longer than the herb, filiform. Flowers in whorls like the Hottonia: pedicels capillary, almoſt the length of the flowers. Bractes to each pedicel two, ovate, minute, even. Calyx bell-ſhaped, acute, five-toothed, almoſt equal, without any wider incumbent tooth. Corollas reflupine, curved, with the lip wider and reflex. Two of the ſtamens the length of the corolla, and two ſhorter [4].

Native of the Cape of Good Hope [5].

6. Stem ſuffruticoſe, three feet high, erect, round, tomentoſe; with ſtraight, aſcending branches. Leaves ſomewhat acute, ſerrate, pubeſcent, brownith-red, waved, petioled, ſmelling like cloves. Flowers white, ſmall, in long, upright, terminating ſpiked racemes. Calyxes hairy, bracted, peduncled [6].

The Great Baſil riſes with a branching ſtalk a foot and half high. Leaves large. Stalk hairy and four-cornered, terminated by a whorled ſpike of flowers, five or ſix inches long. Branches terminated by ſhort ſpikes of the ſame ſort. The whole plant has a ſtrong ſcent of Cloves. Of this there are the following varieties:

1. Purple fringe-leaved.
2. Green fringe-leaved.
3. Great with ſtudded leaves.
4. Large-leaved Baſil.

β. The Common Baſil, uſed in medicine, and alſo in the kitchen, eſpecially in French cookery, riſes about ten inches high, ſending out oppoſite, four-cornered branches from the very bottom. Leaves ovate-lanceolate, ending in acute points, indented on their edges. The whole plant is hairy, and has a ſtrong ſcent of Cloves, too powerful for moſt perſons, but to ſome very agreeable.

The varieties are:

1. Common Baſil, with very dark green leaves and violet-coloured flowers.
2. Curled-leaved Baſil, with ſhort ſpikes of flowers.
3. Narrow-leaved Baſil, ſmelling like Fennel.
4. Middle Baſil with a ſcent of Citron.
5. Baſil with ſtudded leaves.
6. Baſil with leaves of three colours.

There are many other varieties, differing in the ſize, ſhape, odour, and colour of the leaves, [in Europe, but eſpecially in the Eaſt; where Baſil is not only uſed in cookery, but the herb is accounted good in the head-ach, and wandering rheumatic pains; and the ſeeds are reckoned very efficacious againſt the poiſon of ſerpents, both taken inwardly, and laid upon the wound [7].

It was cultivated by Gerarde, in 1596 [8].]

7. The Leaſt or Buſh Baſil is a low buſhy plant, ſeldom more than ſix inches high, branching from the bottom, and forming an orbicular head. Leaves ſmall, ſmooth, on ſhort foot-ſtalks. Flowers in whorls towards the top of the branches, ſmaller than thoſe of the preceding, and ſeldom ſucceeded by ripe ſeeds, in England. Varieties are:

1. Smalleſt Baſil with black purple leaves.
2. With variable leaves.

[Native of the Eaſt Indies. Cultivated by Gerarde in 1596. They are both annual plants, and flower in July and auguſt [9].

8. Stem oleraceous, bluntly-quadrangular, two-grooved, ſparingly branched, a foot high. Leaves bluntly ſerrate, ribbed, wrinkled, like thoſe of Lamium, ſmooth but not ſhining. Petioles gradually finiſhing in the leaf. Peduncles axillary, ſolitary, forming a head of aggregate flowers the ſize of a hazel nut. Common calyx from five to ten-leaved, the length of the flower. Proper perianths tubular, five-cleft, ſeldom four-cleft, equal. Corollas white, very ſmall, ſcarcely to be ſeen by the naked eye: tube ſlender, the length of the calyx: border four-cleft, the upper ſegment ſcarcely concave, bifid, when the whole is five-cleft, reflex. Native of China [10].

9. Stem a foot and half high, erect, brachiate, roundiſh, ſlightly channelled on each ſide, dark purple, muricated with tubercles having a white hair on them. Leaves ovate or ſomewhat oblong, bluntiſh, ſerrate, naked, hairy about the edge and on the nerves beneath, having purple veins on the under ſurface; the upper ones darker. Petioles rough-haired, dark purple. Racemes terminating, ſolitary, erect, dark purple. Bractes petioled, cordate, concave, reflex, deciduous, the length of the calyx, which is rough-haired above the gibbous baſe. Corolla bright purple, ſcarcely larger than the calyx. Filaments white. Anthers yelloviſh. It has ſcarcely any ſmell.

Native of the Eaſt Indies. This as well as the preceding is annual [11].—Introduced in 1758, by Hugh Duke of Northumberland. It flowers in ſeptember [12].

10. From a branched root, ſprings an upright ſtalk, bluntly four-cornered, ſmooth, ſomewhat woody at bottom perennial and browniſh, pale above with a tinge of green. Branches oppoſite, erect at an acute angle, ſomewhat villoſe towards the end. Leaves petioled, ſmooth, appearing dotted on both ſides when examined by a glaſs. Peduncles terminating, erect, long, ſomewhat villoſe, with ſeveral ſix-flowered whorls. Under theſe lanceolate, oppoſite, ciliate bractes. The upper lip of the calyx quite entire. Corolla fleſh-coloured. The whole plant has a very grateful ſmell. Native of Martinico [13].]

11. This riſes with an upright ſtalk near two feet high, ſending out two or four branches towards the top. Leaves about three inches long, and one inch broad in the middle, leſſening at both ends to a point, on foot-ſtalks two inches in length. Flowers in whorled terminating ſpikes; each peduncle ſuſtaining three flowers, which are white, and about the ſame ſize with thoſe of common Baſil. The whole plant has a ſtrong aromatic odour. It grows naturally at Campeachy.

[12. Stem from one to two feet high, roundiſh, purple, brachiate, having ſpreading hairs ſcattered over it: branches ſhorter. Leaves bluntly ſerrate, ſoft, on long petioles. Spikes terminating, in threes, long, narrow, peduncled; with oppoſite, ſquooth bractes, cloſely reflex. Flowers three from each bracte, ſubſeſſile. Calyxes ſmooth, five-cleft, with the upper lip flat, larger, kidney-form, acute. Corolla ſmall, purple; upper lip four-cleft, lower ſimple. Two of the ſtamens appendiculed at the baſe. Style longer than the flower, bifid. The flowers are ſo ſmall as ſcarce to be viſible to the naked eye: they begin to open from the top of the ſpike.

Native of Malabar, and other parts of the Eaſt Indies [14].

13. Stem erect, two feet high, brachiate, four-cornered; the corners ſharp, rugged. Branches oppo-

[1] Linn. ſyſt. [2] Hort. kew from Mill. dict. ed. 6. n. 17. [3] Linn. mant. [4] Lin. ſuppl. [5] Retz. 5. 5. [6] Loureiro. [7] Idem. [8] Hort. kew. [9] Linn ſuppl. [10] Linn. mant. [11] Hort. kew. [12] Jacquin. [13] Linn. ſpec.

&c.

fite, very abundant, erect. Leaves ovate, blunt, grossly serrated, acute, marked with lines. Petioles the length of the leaves, four-cornered, somewhat tagged underneath. Racemes axillary, directed one way, long, erect except at the top, where they nod, especially during the night: flowers in whorls, five together. Calyx five-cleft, the upper segment cordate, the rest subfubulate. Corolla scarcely twice as long as the calyxes, white, four-cleft, like those of Mint, with a purple border, and the upper segment scarcely emarginate. Stamens declined, not longer than the corolla.—It cannot be a *Nepeta*, on account of the lower lip not being crenate; nor a *Mentha*, because the ftamens are declined; for this reaion it is an *Ocimum*, though there are no teeth to the filaments[b].

Native of the Eaft Indies, and perennial, as marked by Linnæus according to the Kew catalogue it is annual, and flowers in july and auguft. It was introduced by John Earl of Bute in 1783.

14. This is a very branching ſhrub; the branches divaricating, villoſe and hoary. Leaves lanceolate, a little narrower at the baſe, ſcarcely petioled, very finely villoſe, hoary, ſmall, like thoſe of wild Thyme. There are rudiments of leafy branchlets from all the axils, and hence the leaves appear to be faſcicled. Raceme terminating, erect, an inch and half long, compoſed of ſix-flowered whorls. Pedicels ſhort, placed on a callus. Bractes minute, ovate, acute, deciduous. Flowers bent down. Calyx half the length of the corolla, very finely villoſe; with the two lower teeth briſtle-ſhaped, the upper ones ovate. Filaments villoſe at the baſe, three times as long as the corolla. It is different from O. filamentoſum of Forſkahl: which ſee under the next ſpecies[c].

15. This is a fragrant undershrub, three feet in height. Stems diffuſed or almoſt erect, round, knotty, cloven, aſh-coloured. Branches oppoſite, ſpreading, ſomewhat four-cornered, with the outer bark lacerated. Shoots four-cornered, annulated, pubeſcent, green. Leaves decuſſately oppoſite, ſharp at both ends, entire at the baſe, papilloſe, almoſt naked, ſomewhat viſcid and rugoſe, concave or convex, ſpreading, having almoſt ſimple nerves; they are fragrant and permanent, from twenty-four to thirty lines in length, and from twelve to fifteen in breadth. Petioles ſpreading a little, four-ſided, compreſſed, rounded on one ſide, flat on the other, ſix times ſhorter than the leaf. Spikes terminating, erect, whorled, bracted, two inches long. Whorls ſix-flowered, the lower ones remote, the upper approximating. Bractes under the whorls oppoſite, ovate-lanceolate, acuminate, crenate, concave, erect, reflex at the tip, falling before the flower expands. Scars from the fallen bractes orbiculate, concave, margined, wide. Flowers oppoſite in threes, on ſhort peduncles, ſpreading a little, white tinged with very pale purple, fifteen lines long comprehending the ſtamens, which are twice as long as the corolla. Calyx ſomewhat bell-ſhaped, erect, ſtriated, villoſe, brownish: upper lip ſtraight, orbiculate, ſcarcely crenulate, ſtretching over the under lip at the ſides: under lip roundiſh, ſcarcely ſhorter, compreſſed laterally, concave, two-horned: the calyx is two lines in length. Corolla ſubvilloſe: tube twice as long as the calyx, prominent a little at top: upper lip larger, reflex, four-cleft, ſegments blunt, ſomewhat toothed, revolute, the two upper ones ſmaller: lower lip ſimple, ſhorter, ſtraight, oblong, concave, reflex at the ſides. Filaments ſcarcely declining under the lower lip, at firſt aſcending at the tip, afterwards revoluſe, purple; the two longer ones ſimple, ſtraight, faſtened to the tube of the corolla towards the top; the two ſhorter inſerted into the baſe of the corolla, converging towards the upper ſide of the tube, jointed where the tube is prominent, bent down at an angle, incraſſated and pubeſcent. Anthers ovate, compreſſed, two-celled, opening at the ſides, peltate, purple. Germ ſuperior, placed on a fleſhy body. Stigma biſid, acute, equal, reclining. Calyx hanging down, cloſed by the converging of the ſides of the lower lip, and thus performing the office of a pericarp. It is ſufficiently diſtinguiſhed by the largeneſs of the flowers, and the length of the ſtamens[d].

It was found by Forſkahl in Egypt, and was brought from Abyſſinia by Bruce, with the Bruceas, Plectranthus punctatus, and other ſcarce plants, before the year 1775. It flowers at the end of ſummer, but ſeldom perfects ſeeds.

16. Stem 2 foot high, upright, brachiate, four-cornered. Leaves ſubſeſſile, ſharply and deeply ſerrate towards the end, leſs ſo or very little towards the baſe. Spikes looſe, whorled, long, terminating the branches. Flowers each on their proper pedicels. Calyxes five-toothed, with the two lower teeth narrower: the two middle lobes of the upper lip of the corolla larger and ſharper. Filaments longer than the corolla, bent down[e].

Native of the iſland of Ceylon—and other parts of the Eaſt Indies. Introduced in 1783, by John Earl of Bute. It flowers in july[f].

17. This plant is annual, pubeſcent and ſweet-ſmelling. Stem thick, bluntly quadrangular. Leaves wrinkled, ſoft, deeply cordate; the lobes approximating, bent in; the ſerratures blunt and unequal: the petioles ſcarcely ſhorter than the leaves. Corollas whitiſh-violet: tube the length of the calyx: upper lip orbiculate, arched; lower four-lobed, or rather three-lobed, with the middle lobe biſid. Filaments ſimple.

Native of the Eaſt Indies, where it was found by John Gerard Koenig, M. D. Introduced in 1781, by Sir Joſeph Banks. It flowers in ſeptember and october[g].

18. Stem pubeſcent. Leaves ovate, petioled, bluntly ſerrate, the petioles, when tender, very tomentoſe. Raceme upright, long. Bractes cordate, ſeſſile, acuminate, even. Pedicels two on each ſide, many-flowered. Calyx minute: upper lip cordate; lower four-cleft, acute, ſlender, the two middle clefts longer. Tube of the corolla erect: border reflex, widening at the throat; upper lip erect, very ſhort, lower elongated, ſickle-ſhaped, involving the ſtamens and piſtil. It differs from its congeners in the flower ſo much, as to be almoſt of a diſtinct genus.

Native of the Eaſt Indies[h], and of the iſland of Tanna in the South Seas[i].

19. This is an annual plant, with the ſtem a ſpan high, erect, eight-grooved, with nodding hairs. Branches very much divaricated, next the root longer, proſtrate. Leaves petioled, ſomewhat hairy, acutely ſerrate, an inch long. Spikes terminating, ſolitary, oblong, formed of whorls. Upper ſegments of the calyx wider, blunter; the two lower ſmaller and more acute. Corolla very ſmall, blueiſh; with the upper lip four-cleft, equal, villoſe along the ſutures; the lower lip a little longer and concave. Stamens declined, ſcarcely marked with any tooth, the length of the corolla. Stigmas almoſt upright.

Native of the Eaſt Indies[k].

20. Stem upright, ſmooth, even. Leaves entire at bottom, ſmooth, pale underneath, veined, two inches wide, three inches long. Petiole a little ſhorter than the leaf, rough-haired underneath at the baſe. Racemes the length of a finger or more. Bractes ovate, acute, biſpid.

21. Stem upright, villoſe, branched. Branches decuſſated, reſembling the ſtem. Leaves acuminate, entire at bottom, ſmooth, purple, an inch long. Petiole the length of the leaf, looſe, villoſe. Racemes looſe, from a finger to a ſpan in length. Bractes oblong, acuminate, ſmooth and even. It is cultivated about Nagaſaki, and flowers there in october and november. An infuſion of the herb is preſcribed in colds and the rheumatiſm: and the Japoneſe eſteem the roots of black radiſhes, and turnep, and various fruits, of a deep red, with a decoction of it.

22. Stem grooved, very finely tomentoſe, two feet high and more. Branches oppoſite, reſembling the ſtem, ſpreading a little. Leaves acuminate, pale and

[a] L'Heritier. [b] Linn. ſyſt. [c] Forſt. herb.
[d] Idem. [e] Linn. mant. [f] Forſter.
[g] Linn. mant. [h] Linn. mant.

wrinkled

wrinkled underneath, the upper ones gradually smaller. Racemes contracted.

23. Stem upright, panicled, a foot high and more, that and the whole plant hairy and rugged. Leaves oblong, acute, serrate, dotted with minute pores underneath. Racemes terminating, a finger's length, with the flowers opposite. Bractes between the flowers, briftle-fhaped.

Thunberg had named this *punctatum* in his Flora Japonica, but altered it to *fcabrum*, there being a fpecies fo named, already in the Supplementum plantarum of the younger Linnæus, and in the fourteenth edition of the Syftema Vegetabilium.

In the former of thefe works it has this fpecific character—ftem round, leaves ovate wrinkled, flowers in fpikes; and is thus defcribed.—It has the appearance of Perilla minor, but the refupine flowers of Ocimum. Stem herbaceous, quite round, a foot high, divaricately branched below, fomewhat hifpid, with oblong, rufous dots. Leaves petioled, ferrate, marked with lines, hairy. Stipules none. Spikes terminating, peduncled. Bractes ovate. Flowers drooping. Corollas blue, the fize of thofe of Thyme: upper lip four-cleft, white; lower compreffed. Stamens as in Ocimum. It is an annual plant, and a native of Abyffinia. It was omitted in its proper place between *minimum* and *capitellatum*.

24. Stem herbaceous, both that and the branches upright and flexuofe, bent in at top, very finely tomentofe, a foot high. Leaves ovate, acute, ferrate, very finely fcabrous, half an inch long. Panicle racemed, contracted. The powder is ufed by the Japoneſe to burn incenſe to their idols.

25. Stem deeply grooved, very finely tomentofe, flexuofe-erect, branched. Branches refembling the ftem, the lower ones more remote, the upper ones roſtlike. Leaves obovate-oblong, very finely tomentofe, an inch long and more. Racemes at the ends of the branches, compofed of many fix-flowered whorls, a finger's length, upright. Near Nagaſaki, in Japoneſe Tſiguſa, or Milk-herb.

The fix laſt fpecies are natives of Japan and have fquare ſtalks[1].]

PROPAGATION AND CULTURE.

The plants, being moſt of them annual, are propagated from feeds, ſown in march, upon a moderate hot-bed, and tranſplanted into another hot-bed, where they muſt be watered and ſhaded until they have taken root; after which they muſt have plenty of air in mild weather, and muſt be watered frequently. In may they ſhould be taken up with a ball of earth to their roots, and planted out either in pots or borders; ſhading and watering them as before.

They may alſo be increaſed by cuttings taken off any time in may, and planted in a moderate hot-bed; obſerving to ſhade and water them during ten days. In three weeks time they will be fit to remove.

The ſeeds are uſually brought from the South of France or Italy every ſpring, becauſe ſome of the ſorts ſeldom ripen their ſeeds in this country in the open air. But ſeeds may be ſaved here, by placing the plants in an airy glaſs-caſe or ſtove in the autumn; ſupplying them with water, and letting them have free air in mild weather.

Some of the more tender ſorts (1. 3, 4. 7. 9. 11, 12, 13. 16. 17, 18, 19.) may be ſown on a hot-bed early in the ſpring, and when the plants come up, tranſplanted on another temperate hot-bed to bring them forward, and when they have obtained ſtrength, tranſplanted into ſeparate pots, and placed in the ſtove.

[The ſhrubby ſorts (3. 14, 15.) may be increaſed by cuttings, planted in a hot-bed.

Leaves lanceolate oppoſite ciliate ſmooth on both ſides.

2. Oedera aliena.
Lin. ſyſt. 796. *ſuppl.* 390.
Leaves linear tomentoſe underneath.

DESCRIPTIONS, &c.

1. Stem ſhrubby, compound, with aſcending branches, covered below with ſcars from fallen leaves, above with green leaves at the ends of the branches. Leaves oppoſite, ſeſſile, narrow, acute, channelled. Calyxes terminating, ſolitary, ſeſſile, with lanceolate leaflets. Ray of the corolla the length of the diſk [a].

Common calyx inverſely conical, imbricated with lanceolate ſpreading and recurved ſcales, ciliate with white lanugo. The partial calyxes contain about fifteen florets, are ſubcylindric, and have many leaflets in a ſingle row; leaflets ſcarioſe, oblong, widening upwards, acuminate, ſhining. Florets in the diſk numerous; in the ray by twos or threes in the outer partial calyxes, the ligulate petal oblong, quite entire. Both florets are fertile. Common receptacle flat, wide,

[a] Linn. amoen.

with linear scattered chaffs: partial receptacle narrow, with linear deciduous chaffs, somewhat shorter than their calyx. Seeds oblong, compressed, obsoletely striated, smooth, bay. Pappus or crown chaffy, many-leaved; leaflets linear-acuminate, shorter than a third part of the seed".

2. This plant has the appearance of Spathelina or Gnaphalium, with the flowers of Calendula, and its genus is yet doubtful. It is an undershrub, not much branched, white-tomentose. Leaves alternate, like those of Rosemary, acute, with one or two sharp teeth at the edge. Flowers terminating, solitary, sessile, the size of Calendula, yellow. Corollets of the ray ligulate, three-toothed, marked with lines, hermaphrodite. Anther pale. Style saffron-coloured, standing out. Stigmas two. Seeds woolly, white, crowned with very many yellow bristles.—Both are natives of the Cape of Good Hope".

OEDERIA. See *Dracæna* and *Lobelia*.]

OENANTHE. (*From* Οἶνος, *the Vine, and* Ἄνθος, *a Flower.*—Oenanthe *of Pliny.* Οἰνάνθη *of Theophrastus and Dioscorides.*)

Lin. gen. n. 352. *Reich. n.* 382. *Schreb. n.* 484. *Tournef. t.* 166. *Juss.* 221. *Gærtn. t.* 22.

Class. 5. 2. Pentandria Digynia.

Nat. order of *Umbellatæ* or *Umbelliferæ*.

GENERIC CHARACTER.

CAL. *Umbel universal* with fewer rays: *partial* heaped with very many rays, but very short, insomuch that there are often none.

Universal involucre many-leaved, simple, shorter than the umbel: *partial* many-leaved, small.

Proper Perianth five-toothed, awl-shaped, permanent.

COR. *universal* difform, rayed. Florets of the ray abortive.

Proper of the disk hermaphrodite, with five, inflex-cordate, almost equal Petals.

Proper of the ray male, with five, very large, unequal, inflex-bifid Petals.

STAM. *Filaments* five, simple. *Anthers* roundish.

PIST. *Germ* inferior. *Styles* two, awl-shaped, permanent. *Stigmas* blunt.

PER. none. *Fruit* subovate, crowned with the perianth and pistil, biparsile.

SEEDS two, subovate, on one side convex and striated, on the other flat, toothed at the top.

OBS. *The Perianth is more manifest in this genus than in the other umbellate plants.*

ESSENTIAL CHARACTER.

Floreta difform: in the disk sessile, barren. *Fruit* crowned with the calyx and pistil.

Root-leaflets wedge-shaped therein, those of the stem entire linear very long simple.

[7. Oenanthe inebrians.
Thunb. prodr. cap. 49.

Pinnas of the lower leaves ovate, of the upper linear, petioles angular.

8. Oenanthe tenuifolia.
Thunb. prodr. cap. 49.

Leaves bipinnate, pinnas linear, the upper ones undivided.

9. Oenanthe ferulacea.
Thunb. prodr. cap. 50.

Leaves superdecompound, pinnules awl-shaped grooved.

10. Oenanthe interrupta.
Thunb. prodr. 50.

Leaves interruptedly bipinnate, segments gash-serrate.

11. Oenanthe exaltata.
Thunb. prodr. 50.

Stems striated, seeds turbinate striated.

DESCRIPTIONS, &c.

These are chiefly aquatic herbs, inclined to be noxious, the third fort very much so. Roots perennial. Some have tuberous roots hanging by threads, as in Spiræa Filipendula; some have a hollow, fistular stalk. The umbels have few rays: the umbellets are globular, with the flowers often sessile, in the ray barren: the radial umbellets in Oe. prolifera are male and pedunicled, the central ones fruitful and sessile. Involucres and involucrels many-leaved: in Oe. fistulosa

[a] Gærtner. [b] Linn. suppl.

fistulosa and crocata there is no involucre; in Oe. globulosa it has only one or two leaves[1].

1. Roots tuberous. According to Haller, they are diffused widely in the water and mud, where they have sometimes bundles of fibres hanging to them; in gardens they are little bulbs. Pollich says, there are long, slender, round fibres, coming out in whorls from the lower part of the stem, which stay it in the water, and that there are also long, jointed, round runners, creeping transversely along the water. Stem from twelve to eighteen inches, or even two feet in height, rushy, upright, striated, smooth, green or glaucous, except at the bottom, where it is red, hollow within: runners similar, prostrate and creeping far and wide. Leaves sheathing, alternate: root-leaves bipinnate, with three or four pairs of pinnas, having the divisions three, four, or sometimes five-lobed, the lobes blunt; stem-leaves pinnate, with lanceolate pinnules, gradually narrower: the nerves of all the leaves fistular at the beginning, widening into the petiole, and embracing the stalk. Peduncles of the umbels very thick and short. The umbel has from two to seven or eight rays, not very distant from each other. Umbellets roundish, close, convex. Linnæus remarks, that the first umbel is trifid, the rest multifid, insomuch that when the summer is advanced, the plant might be supposed different from the vernal one. General involucre either wholly wanting, or of one leaf, but said sometimes to have five leaves: the partial involucre consists of several leaves, or perhaps rather of one leaf, divided into three, five, or even ten short, lanceolate segments. Petals white, in the ray larger, unequal, in the disk smaller, regular, slightly bifid. Stamens three or four times as long as the corollets, and giving the umbellets a feathery appearance. The umbellets, when in fruit, are globular, and hispid all over with the spreading styles[2]. Fruit inversely pyramidal, subpentagonal, grooved, alternate grooves thicker. Ventral part flat. Outer integument fungous, thick[3].

The smell of the plant is unpleasant, and the taste hot and nauseous, as in many of the umbellate plants. The root is said to be poisonous, to have killed a dog within three days, and that out of seventeen Corsican soldiers, who had eaten it, three died, the rest being cured by emetics. Linnæus affirms that kine and horses refuse it, though on experiment it did not appear to be noxious to the former. Schreber informs us that it is left untouched by cattle; and that seems to be the case with us. The seed is slightly aromatic[4].

So little were deleterious effects suspected in this plant, that it was recommended formerly, in common with many umbellate plants, as a diuretic, and good in the stone and gravel: but Linnæus's is a good general rule, that aquatics of this natural order, if not absolutely poisonous, are at least to be distrusted.

Native of most parts of Europe, in ponds, ditches, by river sides, in wet meadows, and marshes, flowering in june and july.

2. The root of this, which has been considered as a variety of the preceding, is composed of many cylindric-ovate white fleshy tubers, collected into a bunch, each terminating in a white fibre at the base. Stem upright, about eighteen inches high, bright green except at the base, where it is red, smooth, grooved, dichotomous, jointed. Leaves alternate, sheathing, triangular, four or five inches long and three inches wide; the lower bipinnate, the upper simply pinnate, with all the segments linear-lanceolate quite entire, on the uppermost leaves longer and directed to one side; all bright green and smooth. Sheaths striated, smooth. Universal umbel flat, with from seven to ten rays: the partial umbel is a little convex, and has more than thirty rays. Universal involucre none, or sometimes, but very seldom, one-leafed. Partial involucre many-leaved, composed of subulate-setaceous leaflets shorter than the umbells[5].

Dr. Withering, who considers this only as a variety of the preceding, says that in the plants which he got in the Isle of Wight, and which correspond with Pollich's figure, the leaflets are three or four inches long, whereas in the preceding they are rarely more than half or three quarters of an inch in length. The bulbs of the roots seem to vary their situation as the plant grows in more or less water, in a thin or a stiff mud, or in a garden soil; so that their being placed in a bundle at the bottom of the stem, or on the fibres of the roots at a greater or less distance, are circumstances too variable to establish a character.

Pollich observed it in the Palatinate, about Lauteren every where in moist meadows, behind Senebach, in drier meadows, about Cusel: flowering in june. Haller and de Saussure in Switzerland. Dodonæus says it is common in brooks, ditches and marshes, and that it will flourish in gardens, even where it is not very moist, but that it is then smaller and shorter.

Parkinson remarks that it flowers and seeds earlier than the other, and that this is usually pull'd before the greater sort is in flower.

Dr. Plot observed it in the ditches about Medley and Binsey common, and almost every where about Oxford: Blackstone on Wandsworth common, Harefield river, and Ham-abbey, Essex: and the late Dr. John Sibthorp, on the banks of the Isis beyond Iffley, and on peat-bogs under Headington Wick copse.]

3. Hemlock Water Dropwort commonly grows four or five feet high, with strong jointed stalks, which, being broken, emit a yellowish fetid juice. The leaves are somewhat like those of common Hemlock, but of a lighter green colour. The roots divide into four or five larger taper ones, which, when separated, have some resemblance to Parsneps, for which some ignorant persons have boiled them.

[Stem rufous: that and the leaves quite hairless. Leaves some pinnate, but more bipinnate: leaflets wedge-shaped, gashed, even, marked with lines, notched on the edges. Peduncles angular, striated. No universal involucre. It seems however, at least sometimes, to have an involucre of five linear leaflets, about half the length of the shorter rays of the umbel, which very readily falling off has not been observed. Rays of the universal umbel longitudinally furrowed. Umbellets nearly globular. General flower not very unequal. Petals white, bent in, acute. Anthers brown*.

Fruit inferior, ovate-cylindric, grooved, crowned. Seeds semicylindric, with five rounded grooves on one side, and flat on the other: integument double; the outer fungous-coriaceous, thick; the inner membranaceous: albumen oblong, narrowing upwards, with three grooves on one side, and one on the other, fleshy, hard, without smell: embryo dicotyledonous, inverted, very short; cotyledons narrow; radicle cylindric, superior*.

Native of several parts of Europe, principally Holland, France and England, on the banks of large ditches, rivers and lakes. As on the banks of the Thames both above and below London; by the side of Lewisham river, beyond the water-works; in marshy meadows between South-end and Sydenham; in Norwood plentifully; between Loompit-hill and Lewisham; near Dulwich College; in the Isle of Dogs the ditches are covered with it. In ditches about Kendal in Westmoreland, where it is called *Dead-tongue*. Between Bishop's Auckland and Wolsingham, and near Stockton. Bent Bogs, near Manchester race ground. Near Bays Water in Oxfordshire. Near Dartford in Kent. Near Bath and Bridgewater in Somersetshire. In Wales. And Mr. Ray says that it grows abundantly, not only in our northern counties, but in Surry, Sussex, &c. in the South. It flowers in june and july.

Gerarde, from Lobel, says, that this plant has a naughty savour, a strong and grievous smell, a hot biting taste, being full of a juice, at first milky, but afterwards turning yellow. It much resembleth Hemlock in property and qualities: for being eaten in salads it did well nigh poison those that ate of it, making them giddy, waxing very pale, staggering and

reeling

ty-ling like drunken men.—Johnſon adds: "Perni-" cious and not excuſable is the ignorance of ſome of " our nine (1633), that have brought, and (as one " may probably conjecture) uſed the roots of this " plant inſtead of thoſe of Peonie; and I know they " are dayly, by the ignorant women in Cheape-ſide " ſold to people more ignorant than themſelves, by " the name of *Water Lovage*."

Ray, in his hiſtory, (1686) ſpeaks doubtfully of the malignity of Hemlock Water Dropwort, and leaves it to further examination: but in the third edition of the Synopſis (1724) it is ſaid, that no doubt remains of the poiſonous quality of theſe roots, and reference is made to the German Ephemerides, and the Obſervations of Stalp. vander Wiel.

Dr. Withering ſays the whole of this plant is poiſonous; and Dr Pulteney remarks, that the root is the moſt virulent of all the vegetable poiſons that Great Britain produces. Many inſtances of its fatal effects are recorded, wherein it has been eaten for water-parſneps, or celeri, which laſt it reſembles in its leaves[r]. Mr. Lightfoot relates, that he had heard the late Mr. Ehret, the botanic painter ſay, that while he was drawing this plant, the ſmell rendered him ſo giddy, that he was ſeveral times obliged to quit the room, and walk out in the freſh air to recover himſelf; but that having opened the door and windows of the room, the free air enabled him to finiſh his work. I always experience the ſame effect from Henbane. Mr. Lightfoot adds, that he has ſeen a large ſpoonful of the juice of this plant given to a dog, which made him very ſick and ſtupid, but in about an hour he recovered; and that he has ſeen a goat eat it with impunity: ſheep alſo are ſaid to eat it; kine and horſes to refuſe it.

An infuſion of the leaves, or three tea ſpoonfuls of the juice of the root, taken every morning, effected a cure in a very obſtinate cutaneous diſeaſe, but not without occaſioning very great diſturbances in the conſtitution. The country people in Weſtmoreland apply a poultice of the herb to the ulcer which forms in the fore-part of the cleft of the hoof in horned cattle, and is called the foul[s].

It may be ſafely uſed externally, but internally it ſhould be taken with caution, as is evident from the accounts given above, and others recited by Mr. Howell, and the late Sir William Watſon in the Philoſophical Tranſactions. The former of theſe gentlemen ſays, that two French priſoners at Pembroke died by eating the root, that the inhabitants call it five-fingered root, and that it is much uſed there in cataplaſms for the fallon, or worſt kind of whitlow. In n. 238 of the Philoſophical Tranſactions a caſe is related of eight young lads near Clonmell in Ireland, where this plant is called *Tabowe*, miſtaking its roots for the Water-Parſnep: five of them died. Dr. Allen, in his Synopſis Medicinæ, mentions an inſtance of four children, who eat of theſe roots, but by proper care did well: and another of a pig's dying in convulſions, from eating ſome of theſe roots, which it had grubbed up. Mr. Miller informed Sir William Watſon that a whole family were poiſoned with this plant at Batterſea.

The method of cure is to empty the ſtomach and inteſtines as ſoon as poſſible, and then to cauſe the patient to ſwallow large quantities of oleaginous fluids. This is attended with difficulty, becauſe the jawa are, as it were, locked together by the violence of the ſpaſm.

The more caution is neceſſary reſpecting this plant, becauſe it is not uncommon in ſome places, its appearance and ſmell reſemble ſmallage or celeri, and the roots have not any flavour diſagreeable enough to deter perſons from eating them.

Lobel is the firſt who has given a ſmall figure and a tolerable deſcription of this plant. Dodonæus's figure is execrably bad, and is copied by Gerarde and Parkinſon. The figures of John Bauhin, Matthiolus and Morriſon give us ſcarcely any other idea of the plant, than that it is an umbelliferous one, with roots divided like thoſe of Aſphodel. Morriſon's is the beſt. Jacquin has given a good coloured figure of it, and it cannot be miſtaken from the plate engraved by Myndle from a drawing of Ehret's, which accompanies Sir William Watſon's diſſertation on this plant, in the Philoſophical Tranſactions; where it may alſo be compared with Cicuta virola, another of our moſt poiſonous plants.

Mr. Ray's deſcription of Oenanthe crocata is taken from Lobel. Morriſon's deſcription, in his Umbelliferæ, is exact and copious.

4. Root perennial, conſiſting of ſeveral tubers, which are round, narrowing to each end, long, of a dirty brown on the outſide, white within. The whole plant is ſmooth. Stem herbaceous, a foot and half in height, upright, little branched, green, angular-ſtriated. Leaves ſubtripliçate-pinnate, from a round midrib, ſcarcely ſtriated, ſheathing at the baſe: leaflets blunt, gaſhed, ſubovate or rather roundiſh. Univerſal involucre none, or at moſt of one or two awl-ſhaped leaves: partial of ſeveral lanceolate-linear acuminate, unequal, ſhort, very ſpreading leaflets. Univerſal umbel has from five to eight rays, long, ſtriated, thickiſh, ſpreading: partial at firſt very cloſe, convex, ſmall, the florets ſeſſile; but afterwards the outer florets ſtart out and have rays, ſome of them an inch long. Theſe are male and have the petals very unequal. The central florets are hermaphrodite, fertile and equal. Petals white, erect, longly cordate, bent inwards, awl-ſhaped and very long at the tip. Filaments longer than the corolla. The fruits of each umbel make a compact hard hemiſpherical head, rendered rough by the ſtiff calycine leaflets: each fruit is inverſely conical, with little taſte and no ſmell, pale, angular, bluntly grooved, crowned by the calyx. Seeds ſmooth, flat on one ſide, five-grooved on the other[t].

Native of Sicily and Italy. Cultivated in 1739, by Mr. Miller. It flowers in june and july[u].

5. Roots like thoſe of Navew, perennial, branched. Stem a foot high or more, branched, angular at the baſe, and often purple. The firſt root-leaves ternate or quinate, with ſome of the leaflets lanceolate, others wedge-ſhaped, entire bifid or three-lobed, veined, very ſmooth. The next and lower ſtem-leaves are lanceolate, bipinnate, the pinnules and leaflets oppoſite, lanceolate, bifid or trifid, acuminate. Sheaths of the petioles wide, membranaceous, nerved, at the top running into the petiole, but not lobed. The reſt of the ſtem-leaves pinnate; with narrower, longer, ternate leaflets. The uppermoſt, and thoſe on the branches, alſo pinnate, but with the leaflets quite ſimple, much narrower and longer. Peduncles oppoſite to the leaves, round, very ſlightly ſtriated, the length of the internodes, almoſt four inches long. Umbels of three or four rays, nearly half an inch in length, unequal. Univerſal involucre either wanting, or having one or two leaves at moſt. Umbellets cluſtered, with from twelve to fifteen florets. Leaflets of the involucels ſubulate-lanceolate, equal, the length of the florets[v]. Fruit ſmall, ovate-globular, within a little crown formed of the permanent calyx produced into a conical ſtyle-bearing tubercle. Seeds ſubhemiſpherical, with three thicker ridges along the back, beſides the margin; flat on the belly. Outer integument thick and ſomewhat fungous. Embryo minute, roundiſh[w]. The fruit is larger than a Coriander. It has more the appearance of the next ſpecies than any other, but it is eaſily diſtinguiſhed from that by the whole leaves being lanceolate, not triangular, and the ſtem being leſs branched[x].

Native of Portugal. Cultivated in 1739, by Mr. Miller. It is biennial, and flowers in june and july[y].

6. Roots cylindric, cluſtered, fibrous, with bulbs or tubers hanging upon long peduncles. Stems ſhort, a hand or half a foot in height, angular. Root-leaves like thoſe of Parſley, but thicker, bipinnate, broad, with wedge-form, gaſhed, divided leaflets. Stem-

[r] Miſſel. Tranſ. Gentl. magaz. july 1747, march 1755, ſept. 1758. Withering.

[s] Jacquin. [t] Hort. kew. [u] Gouan. [v] Gærtner. [w] Gouan. [x] Hort. kew. [y] Gouan.

leaves left compound, scarcely bipinnate; with linear, channelled, very long leaflets. Umbel unequal. Both involucres subulate-setaceous. Corollas white, little rayed[*].

Relhan says that the stem is from two to three feet high. According to Scopoli, it is the ray and not the disk in this species that is abortive. Haller remarks, that the outer rays of the partial umbel are very long, and the florets barren. The calycine teeth, as Scopoli observes, are unequal, two being larger than the other three. The styles are upright.

Villars remarks that the leaves vary much; those under water being wide, thick, bipinnate and rounded; the others straight, much narrower and longer: umbels solitary, on straight stems, two or three feet high.

Gærtner describes the fruit as being turbinate-cylindric, crowned with a width calyx, with a white callous ring at the base: back convex with three streaks, and the margin thickened at the sides: belly flat. Embryo minute, roundish.

Native of the southern part of Europe and England, in marshes, especially near the the coast, as at Quapload in Lincolnshire near Spalding. Hinton-moor in Cambridgeshire. Bulvan-Fen, Essex. Near Mortlake. Between Sydenham and South-end.

7, 8, 9, 10, 11. Natives of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

All these plants naturally grow in moist places, their seeds therefore should be sown upon a moist soil in autumn soon after they are ripe. [The first, second and sixth sorts will do very well in the common ground; but the third requires mud to grow in to any purpose.

OENANTHE. See *Sefeli*, *Sison*, *Sium*, *Thalictrum*.

Leaves lanceolate blunt ſmooth ſubpetioled ſtems proſtrate (aſcending) capſules acute-angled.

DESCRIPTIONS, *&c.*

[Theſe are herbaceous, hardy, biennial plants, for the moſt part; the ninth is marked as annual, ſome are perennial, and the tenth is called ſhrubby, though hardly ſo in reality: ſome of the herbaceous ones are inclined to be woody at bottom. The leaves are alternate. The flowers axillary and ſolitary[*].

1. Root fuſiform, fibrous, yellowiſh on the outſide, white within, biennial. From this, the firſt year, ariſe many obtuſe leaves, which ſpread flat on the ground. From among theſe, the ſecond year, the ſtems come out, three or four feet high. The ſpecimen before me (Auguſt 8th, 1798) is conſiderably more than five feet in height, upright, of a pale green colour, the thickneſs of a finger, not hollow but pithy, angular, ſlightly pubeſcent and rugged, tinged with purple, eſpecially towards the bottom, branched alternately almoſt from the ground. Root-leaves run down into a three-ſided petiole an inch in length. Stem-leaves ſeſſile, bright lightiſh green, pubeſcent on both ſides, waved a little

[*] Linn.

[*] Juſſieu.

about the edge, and having a few ſmall teeth near the baſe; they are from five to ſeven inches in length and two inches in breadth, having a conſiderable midrib running the whole length, very wide and tinged with purple towards the baſe, at the back very prominent, with white nerves ſpringing from it, and curved towards the point. The flowers are produced all along the ſtalks on axillary branches, and in a terminating ſpike. The leaves on the former are ſimilar to the ſtem-leaves, but much ſmaller, being not more than two inches long, and little more than half an inch in breadth. Flowers ſolitary, each being ſeparated by a leaflet or bracte, wider in proportion at the baſe than the proper leaves, and drawn more to a point, diminiſhing gradually towards the top of the ſpike, till they become linear, ſcarcely half an inch in length, and a line in breadth. Germ ſeſſile, an inch long or more; on the top of this is the tube of the calyx, from an inch to almoſt two inches in length, and narrow, ſpreading out at top into four acute ſegments, villoſe on the outſide, an inch in length, bent down by pairs when the corolla expands, and then rolled inwards. Scopoli remarks, that there are four, oblong, yellow tubercles growing to the baſe of the calyx. Corolla bright yellow, from an inch and half to near two inches in diameter, ſpreading out quite flat in the evening, petals roundiſh, blunt, ſometimes emarginate, crenate, and waved. Stamens much ſhorter than the corolla. Filaments ſhorter than the ſtyle, yellow. Anthers four lines in length. Stigmas yellow, mealy, one commonly longer than the others. Germ four-grooved.—Capſule not crowned, ſubcylindric, obſcurely four-cornered, pubeſcent with very ſoft villoſe hairs. Seeds numerous (fifty in one cell), lying over each other in a double row, oblique, in a manner half-mooned, flat on both ſides, fungous, ferruginous [a].

The flowers uſually open between ſix and ſeven o'clock in the evening, whence this plant is called Evening or Night-Primroſe. The mode of their expanding is curious. The petals are held together at top by the hooks at the end of the calyx, the ſegments of which firſt ſeparate at bottom and diſcover the corolla, a long time before it acquires ſufficient expanſive force to unhook the calyx at top; when it has accompliſhed this, it expands very faſt, almoſt inſtantaneouſly to a certain point, and then makes a ſtop, taking a little time to ſpread out quite flat: it may be half an hour from the firſt burſting of the calyx at bottom to the final expanſion of the corolla; which commonly becomes flaccid in the courſe of the next day, ſooner or later according to the heat or coolneſs of the weather. The uppermoſt flowers come out firſt in june, the ſtalk keeps continually advancing in height, and there is a conſtant ſucceſſion of flowers, till late in autumn.

It is a native of North America: and was firſt ſent from Virginia to Padua in 1619. It was cultivated here in 1629, as appears from Parkinſon. He gave it the name of Tree-Primroſe. It is now become a denizon of ſeveral parts of Europe; but though it is very common in gardens with us, I have never ſeen it in a wild ſtate. The roots are eaten in ſome countries in the ſpring.

2. This is a biennial plant as well as the preceding, and ſeveral of the other ſpecies, but the ſtem is more ſhrubby. It is alſo a native of North America, but was not known here till it was introduced by John Fothergill, M. D. in 1778. It flowers in july and auguſt [b].

3. The apex of the fruit is crowned with an eight-cleft margin, not four-cleft, as in the firſt ſpecies, which it very much reſembles [c]. Stalks red, ſet with rough protuberances. It does not riſe ſo high as the firſt, the leaves are narrower, and the flowers are ſmaller. [Leaves ſpear-ſhaped and ſomewhat toothed, leſs ſoft. Calyx four times ſhorter than its tube, with a toothleſs below the tip, hence before the calyx unfolds the points in this are diſtant. Sides of the petals diſtant. Petals leſs by half than thoſe of the common ſort [d].

[a] Gaertner. [b] Hort. kew. [c] Linn. ſpec. [d] Linn. ſyſt. and Comm. gott.

Native of North America, and biennial as that is: flowering from june to auguſt. Native alſo of Japan, according to Thunberg. According to the Kew catalogue it was introduced in 1775, by John Earl of Bute.]

8. This differs from the firſt in having ſhorter ſtalks, narrower leaves and ſmaller flowers; from the ſecond, in having ſmooth ſtalks, of a pale green colour.

[4. This reſembles the parviflora, but the mouth of the fruit is not eight-cleft. The ſtem has red dots ſcattered over it. The corolla is only half the ſize and paler, with the petals emarginate but not biffid. Stamens equal to the corolla or longer, never ſhorter.—Native of Canada.

5. Root biennial. Root-leaves numerous, broad-lanceolate, toothletted, pubeſcent with a white rib, obliquely nerved. Stems uſually five, ſpringing out below the root-leaves, quite ſimple, aſcending, rough-haired, green with long ſpreading white hairs. The central ſtem grows up later. Stem-leaves ovate-oblong, ſeſſile, like the root-leaves. Flowers axillary from the upper leaves, with the germ and calyx hairy. Tube of the calyx remarkably elongated, three times as long as the border. Petals yellow, obcordate two-lobed, the ſame ſize with the common ſort or larger, diſtant at the ſides, turning reddiſh the ſecond day. Fruit like that of *biennis*, but longer, and narrower at bottom, with the mouth converging and leſs rugged.

It has many of the above circumſtances in common with the firſt ſpecies; that differs from this in having the ſtem upright, the ſide branches ſcarce apparently hairy, the petals approximating, ſcarcely emarginate, never biffid, and the tube of the calyx ſcarcely twice as long as the ſegments. It differs from *Oe. mollifſima* in the ſtem not being branched, the leaves wider, and not ſoftly pubeſcent: from *Oe. parviflora* in the ſtem not being red, and the flowers much larger [e].

Mr. Curtis remarks, that luxuriant ſpecimens exceed five feet in height, that the flowers are uncommonly large and ſhowy, and continue blowing from july to october.

Native of Buenos Ayres. Introduced in 1776, by Chevalier Murray [f].]

6. This has a ſhrubby ſtalk more than two feet high, hairy, with narrow-lanceolate, ſeſſile leaves, a little waved on their edges, and ending in acute points. Flowers axillary like the other ſorts, at firſt pale yellow, but as they decay changing to an orange colour, ſmaller than thoſe of Oe. biennis. Seed-veſſels ſlender, taper, hairy.

[According to Dillenius, the ſtems are uſually eighteen inches high, round, upright, ſomewhat duſky at bottom, pale green above, branched a little from the bottom. Leaves toothed here and there on the edge, ſoftly pubeſcent, green on both ſides with a white midrib, and oblique veins. Flowers ſomewhat ſmaller than thoſe of the common ſort, but on a longer peduncle: petals wrinkled, approximating. The petals and leaflets of the calyx do not fall off, but wither on the fruit, and fall with the pedicel, which cannot be conſidered as the tube of the flower, ſince it is not hollow. Anthers at firſt upright, but afterwards tranſverſe. The capſules increaſe in length after the flowers fall; they are round, ſtriated but leſs deeply than in the common ſort, longer and thicker. The whole plant is ſoft, peduncles, capſules, and all, eſpecially in a wild ſtate, when the leaves are narrower and all the parts ſmaller than in a garden.

This is alſo a biennial plant, native of Buenos Ayres. It was cultivated before 1732 in the Eltham garden, belonging to James Sherard, M. D. being raiſed there from the ſeed of ſpecimens ſent from America. It flowers from june to october.

7. This rarely exceeds a foot in height. Its roſe-coloured flowers expand during the whole of the day, and are produced during moſt of the ſummer months. Of the eleven ſpecies, ſays Mr. Curtis, this only and the next have red or purple flowers, the reſt are yellow. He obſerves alſo that this is ſcarcely entitled to

[e] Linn. mant. [f] Hort. kew. [g] Idem.

the diſtinction of a perennial.—Native of Peru. Introduced by Monſ. Thouin in 1783[p].

8. This is diſtinguiſhed by the glaucous appearance of its foliage, the purple hue of its corolla, and the dark colour of its ſtigma. It is about two feet high, and produces abundance of fine purple flowers in july and auguſt, open, like thoſe of *roſea*, during the day. The ſeeds ripen in ſeptember[q].

This plant is not in the *hortus kewenſis*, but it appears from Mr. Donn's Cambridge catalogue, that it was introduced from the weſtern coaſt of North America, in 1791. It is an annual, and a very ornamental ſpecies. Mr. Donn names it *humilis*.

9. Root annual. Stem ſimple, round, a foot high, upright, nodding at top; when young hairy, when old ſmoothiſh; branches alternate. Leaves ſeſſile, broad-lanceolate, naked, oblique. Flowers ſeſſile, hairy on the calyx and germ. Calyx acute, mucronate below the tip; the tube aſcending. Germ before flowering-time declined. Petals yellow, obcordate, the ſame length with the leaves of the calyx. Capſule cylindrical, quadrangular with the angles flat, truncate with the top deeply excavated and four-cleft; the lobes emarginate. It ſleeps during the night, with the upper leaves hollowed[r].

Native of North America. Introduced in 1770, by Monſ. Richard[s].

10. This is a perennial, but altogether herbaceous, at leaſt with us, and therefore improperly named *fruticoſa*. The flowers which are large and ſhowy, though they open in the evening, remain expanded during moſt of the enſuing day. The flower-buds, germ and ſtalk are enlivened by a richneſs of colour which contributes to render this ſpecies one of the moſt ornamental and deſirable of the genus[t]. In cloudy weather the common Tree-Primroſe keeps open during the whole of the day ſubſequent to the evening of its expanſion.

Mr. Curtis's *frutioſa* cannot be the ſame with that of Linnæus, who deſcribes the flowers as ſmall and white, the tube filiform and very narrow; the calyx purple, four-leaved, but generally ſmelling on one ſide; the capſule with four acute compreſſed angles; the leaves thinly toothed.

Native of Virginia. Cultivated in 1739, by Mr. Miller, as appears from Rand's catalogue, for it is not in the Dictionary[u].

11. Root perennial, fibrous. Lower leaves ovate, ſmall, cloſe to the ground. Stalk ſlender, near a foot high. Leaves ſmaller, light green, ſeſſile, ending in blunt points. Flowers ſmall, bright yellow. Capſules ſhort, ovate, furrowed.

This is diſtinguiſhed from all the ſpecies with yellow flowers by the inferiority of its ſize; in its moſt luxuriant ſtate rarely exceeding a foot in height, and commonly far more humble. It ſends up many flowering-ſtems, producing bloſſoms from april to july, open in the morning as well as evening. The ſtalks are rather aſcending than proſtrate[x].

Linnæus deſcribes the ſtem as a palm in height, herbaceous, round, flexuoſe, very much divaricated: leaves elliptic-lanceolate, quite entire: flowers erect, ſubſeſſile, with yellow, obcordate petals, marked with lines: capſules obovate, blunt, octangular, with four of the angles wider and compreſſed.

Native of North America. Cultivated in 1757, by Mr. Miller: who had the ſeeds from Monſ. Richard[y], the King of France's gardener at Trianon.

There are ſeveral other ſpecies of Oenothera known, but not yet ſufficiently aſcertained. Two are figured by Jacquin in his magnificent work entitled Icones Plantarum Rariorum. One by Mr. Curtis. And I raiſed another from ſeed given me by Governor Phillip, on his return from his government. Mr. Donn cultivates ſixteen ſorts, in the botanic garden at Cambridge.]

PROPAGATION AND CULTURE.

The firſt and ſome of the other ſpecies (3. 4. 9), are very hardy biennial plants. Sow the ſeeds in autumn; when the plants come up, thin them, and keep them clean: the following autumn, tranſplant them to the places where they are deſigned to flower. As the roots ſtrike deep in the ground, care ſhould be taken not to cut or break them in removing. They will thrive in almoſt any ſoil or ſituation; and will flower even in London, better than moſt other plants. If once introduced, and the ſeeds permitted to ſcatter, there will be a ſupply of plants without any care.

2. 5. 6. 7. Are more tender, and commonly conſidered as green-houſe plants, but as they produce flowers and ſeeds in the open air, the plants are ſeldom preſerved.

[5. Is an annual, (or rather biennial) of ready growth, and very productive of ſeeds, ſome of which ripen early. Sow them in the open border, where they are intended to flower, in march or the beginning of april. A ſingle plant is ſufficient for one ſpot. Put a ſtick to it early of four feet in length, to which tie its branches, when about a foot long[z].]

6. Will come up from ſcattered ſeeds like the firſt.

[7. May be increaſed either by cuttings or ſeeds. Theſe are plentifully produced. Sow them in the ſpring with tender annuals: when the plants have acquired a proper age and the ſeaſon is favourable, plant them out ſingly in the open border.

8. Is an annual of ready growth. Sow the ſeeds and tranſplant, as directed for the preceding ſort.

10. May be increaſed by ſeeds, by parting the roots and by cuttings. It is hardy enough to bear the open air[a].]

11. This may be propagated by parting the roots or by ſeeds. The beſt time for the former is the ſpring: but ſeeds ſhould be ſown in the autumn, in pots, placed under a hot-bed frame in winter. In the ſpring the plants will appear: when fit to remove, plant a few in ſmall pots, to be ſheltered under a common frame in winter: plant the others in a ſheltered border, where they will endure the cold of our ordinary winters very well, and the following ſummer produce flowers and ſeeds in plenty. The ſeedling plants will be much ſtronger, and flower better, than thoſe from offsets.

DESCRIP-

DESCRIPTION, &c.

This is a tree, with flaccid branches, wrinkled like those of Viſcum or Miſſelto, alternate. Leaves ovate, ſmooth, veinleſs, alternate, quite entire, petioled. Peduncles very ſhort, ſomewhat branched, from the axils of the leaves [a].

Branches angular with flexuoſe decurrent lines, ſmooth, covered with a yellowiſh green bark, very finely wrinkled across. Leaves two or three inches long, ovate-lanceolate, very ſmooth and even, with a groove along the middle above, very finely nerved, ſcarcely veined, blunt. Racemes axillary, quite ſimple, ſhorter than the leaf, uſually ſolitary, very ſeldom in pairs. Peduncles filiform, after the flowers are fallen toothletted [a].

Berry half covered with the permanent calyx and corolla, ſmall, the ſize of a radiſh ſeed, black, with a firm and as it were coriaceous fleſh, the pulp of the cells gelatinous. Receptacles, very thin membranaceous ligules, from the central angle of the cells, radiating towards the periphery [a].

Gærtner is of opinion that the Olax of Linneus, which agrees with his ſpecimens except in the nectaries, is different from the Arbor ſtercoraria of Burmann, and the Malla-holla of Hermann.—Native of Ceylon.]

OLDENLANDIA. (*So named by Plumier, in memory of Henr. Bernh. Oldenland, a Dane, who collected plants at the Cape of Good Hope in* 1695. *They came into the poſſeſſion of Burmann, and there is an account of them in the ſixth volume of the Amœnitates.*)

Lin. gen. n. 154. *Reich. n.* 162. *Schreb. n.* 205. *Gærtn. t.* 30. *Juſſ.* 198.

Claſſ. 4. 1. Tetrandria Monogynia.

Nat. order of *Stellatæ*. *Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* four-parted, the parts awl-ſhaped, ſuperior, permanent.

COR. one-petalled: *tube* cylindrical, cloſed by a beard: *border* four-parted, acute, ſpreading, a little longer than the calyx.

STAM. *Filaments* four, ſimple, within the tube. *Anthers* ſmall.

PIST. *Germ* roundiſh, inferior. *Style* ſimple, the length of the ſtamens. *Stigma* bifid, obtuſe.

PER. *Capſule* twin, roundiſh, two celled, opening between the teeth of the calyx.

SEEDS numerous, very ſmall.

OBS. *According to Schreber, it ſcarcely differs from* Hedyotis, *and therefore one of the genera might be ſpared. There is a difference however in the calyx, corolla and receptacle.*

ESSENTIAL CHARACTER.

Cal. faſtened to the pericarp, with four free awl-ſhaped teeth at top. *Cor.* one-petalled four-cleft. *Capſ.* inferior, two-celled. *Recept.* free, faſtened to the partition by the baſe only.

DESCRIPTION, &c.

Theſe are herbaceous plants, ſome of them inclined to be woody. Pedunckes terminating or axillary, one or many-flowered. Leaves joined at the baſe by a ciliary sheath [a].

1. Stems about a foot high, ſimple jointed, even, round, with a groove on each ſide. Leaves oppoſite, ſeſſile, narrow-lanceolate with the midrib ſcored, acuminate, rugged. Stipules membranaceous, divided into briſtles, as in Spermacoce, ſome of which are capillary, and longer than the flowers. Capſule roundiſh, two-celled, many-ſeeded, connate with the four acuminate leaflets of the calyx [b].—Native of Amboina and Jamaica, on open hills.

2. Stem creeping, filiform, branched, jointed, rooting at every joint, even. Leaves oppoſite, ſubpetioled, quite entire, even, ſmall. Flowers axillary, ſolitary, alternate, ſubſeſſile. Capſule ſubglobular, covered with blunt, hollow pellucid hairs, two-celled, many-ſeeded.

Stem ten inches high, ceſpitoſe, herbaceous, branched, procumbent, jointed, creeping. Leaves linear-lanceolate, quite entire, ſmooth, oppoſite, ſeſſile. Flowers white, axillary, ſolitary, on very ſhort pedunckles. Corolla four-cleft, bell-ſhaped. Capſule calycine, two-celled, many-ſeeded, opening irregularly. Rumphius's figure repreſents the leaves wider and rounded, whereas they appeared to Loureiro to be ſtrict and acute.

Native of the Eaſt Indies, and of China near Canton [c].

[a] Juſſieu. [b] Linn. mant. [c] Loureiro.

3. This resembles the preceding very much, but the capsule is smooth.—Native of the Cape of Good Hope, where it was found by Thunberg [a].

4. Stems branched and creeping. Leaves opposite, lanceolate-ovate, subpetioled, quite entire. Flowers axillary, few, each on its proper peduncle. Germs hispid.—Native of Virginia and Jamaica. In the latter, according to Browne, it is found frequently in the waters, and then it grows of a length proportioned to the depth of the stream, with which it yields and bends: both leaves and stalks are then of a reddish colour. Sometimes it is found upon the banks, and then it is of a green colour and a creeper, generally running more or less according to the quantity of moisture [b].

5. Stem herbaceous, erect, jointed, dichotomous. Leaves quite entire, narrower at the base, ending in the petioles, opposite. Flowers two together at a joint on elongated peduncles, pendulous; or a bifid peduncle bears two flowers.—Native of the East Indies. Annual [c].

6. This is a small biennial, rarely triennial plant. Root very long, from one to two feet, slender, with few lateral fibres, when fresh the bark is orange-coloured; in the cultivated sort it is longest, and with fewer fibres. Stem in the cultivated sort erect, round, jointed below, very ramous, somewhat scabrous, from six to twelve inches high. Branches axillary, the under opposite, decussated, spreading horizontally, and nearly as long as the stem, above alternate or in pairs from the axils.—In the wild sort there is scarce any stem, but many diffuse scraggy branches, with their flower-bearing extremities erect. Leaves opposite, or by threes or fours, sessile, linear, pointed, scabrous, spreading, from half to three quarters of an inch long, by one-third of an inch in breadth. In the axils of the principal leaves are generally fascicles of smaller leaves. Stipules connecting, ciliate. Flowers terminating, small, white, very numerous, the whole forming a large umbel, composed of small three-cleft umbellets. Bractes minute, awl-shaped.

Native of the East Indies, growing in very light dry sandy ground near the sea: flowering during the latter part of the wet season; and the seed ripe in january. It is much cultivated on the coast of Coromandel, where its roots descend to a great depth in the sand. It is used in dying red, purple, a deep clear brown, orange, and to paint the red figures on chints; of all which Dr. Roxburgh has given a full account.

The woody part of the Chay root, as it is called, is white and tasteless; it is the bark only that is possessed of the colouring principle: when fresh it is orange-coloured, tinges the spittle yellow, and leaves a slight degree of acrimony on the point of the tongue for some hours after chewing: to appearance it loses its yellow colour in drying, but still retains the above property on being chewed. It impregnates cold water or spirits with a straw colour; to boiling water it gives a brownish porter colour. The watery infusions and spirituous tinctures are changed into a bright and deep red by alkaline substances; and are rendered paler, or nearly destroyed, by acids. The colouring powers of this root is said to improve by keeping three or four years. When the wild sort can be had in any quantity, it is esteemed one-third or one-fourth stronger, and yields a better colour: and when these roots can be had of two years growth, they are reckoned still better.

This plant is the Thseri-vello of the Telingas; and the Saya-ver, or Imburel of the Tamuls. The Telinga physicians do not give any part of the plant a place in their Materia Medica; but the Malabar physicians say that the roots cure poisonous bites, colds and cutaneous disorders, and warm the constitution [d].

This plant has been introduced into the island of Jamaica.

7. This is a diffused plant. Leaves opposite, petioled, quite entire, veined, nerved. Umbels few-flowered, peduncled. Calyxes bell-shaped.

[a] Linn. suppl. [b] Linn. spec. [c] Linn. syst. [d] Rexburgh.

Native of Java, where it was found by Thunberg [e].

8. This is a low annual plant, seldom above three or four inches high, dividing into many branches which spread near the ground. Leaves long, narrow and opposite. Flower-stalks axillary, an inch or little more in length, and dividing into three or four smaller foot-stalks; on the top of each of these stands one small white flower.

[According to Browne, it rises generally to the height of ten or fourteen inches: the peduncles are sometimes simple, but oftener branched; and rise immediately from the axils, or shoot from the top of the smaller ramifications: all the parts of the plant are very delicate.

Linnæus describes the stems, to be almost prostrate, ascending, four-cornered, even, with opposite branches. Leaves opposite, even, marked with a longitudinal line, the length of the internodes. Stipules opposite, very blunt, connecting the leaves, with three awns at the tip, as in Spermacoce; by which also it is allied to Houstonia. Peduncles alternate, solitary, lateral, filiform, naked, each within each stipule, the length of the leaf, terminated by an umbel of about four flowers, without an involucre. Flowers white.

According to Gærtner, the capsule is inferior, small, crowned with the distant toothlets of the calyx, subglobular, twin, two-celled, opening at top by a transverse chink: partition contrary to the chink. Receptacle oblong, fungous, excavated, having a lateral peduncle, inserted into the lower part of the partition, free above, one to each cell. Seeds very numerous and small, subglobular, shagreened, ferruginous.

Native of Jamaica. Introduced before 1739, by Mr. Robert Millar [f].

9. Stem almost upright, even, dichotomous. Leaves opposite, acute, quite entire, even. Panicle leafless. Fruits even [g].

Stem herbaceous, manifold, diffused, suberect, six inches high. Leaves lanceolate, subsessile, smooth, somewhat fleshy. Flowers purple, on a long common peduncle. Capsule calycine, twin, turbinate-round, two-celled, many-seeded, crowned with the four sharp teeth of the calyx [h].—Native of the East Indies.

Loureiro remarks, that Mollugo zeylanica of Burmann, though it seems like this in the flower, yet by no means agrees with it in its stellate leaves, and indeed it is doubtful whether it be an Oldenlandia.

10. This resembles Oldenlandia biflora, but is larger, and half a foot high. Stem erect, pubescent. Leaves opposite, sessile, quite entire, pubescent. Peduncles axillary, solitary, simple, bifid at top, shorter than the leaves. Petals five, small, white tinged with red. Calyx five-toothed, pubescent. Stamens five. Pistil one.—Koenig sent it from Tranquebar.

11. The appearance of this is different from that of the Oldenlandias. Stems branched, decumbent. Leaves entire, sessile. Flowers axillary, sessile or on very short peduncles. Calyx five-cleft with a globular tube. Petals five, minute, white. Stamens five. Styles two. Capsule two-celled, two-valved.—Koenig sent this also from Tranquebar.

12. Root branched, slender. Stems depressed, angular, branched. Leaves opposite, petioled, broad-ovate, quite entire, somewhat hairy. Flowers on short pedicels. Fruit twin, four-toothed.—Sent from the East Indies by Koenig [i].

13, 14. Natives of the island of Tonga-tabu in the South Seas.

15. Native of the East Indies; and of the island of Tanna in the South Seas [k].

16. Stem herbaceous, manifold, eight inches high. Leaves quite entire, smooth, sessile, opposite. Peduncles erect, terminating. Corolla four-cleft, purple. Stigma lanceolate. Capsule calycine, twin, two-celled, many-seeded. Stamens four, short.—Native of the Eastern coast of Africa [l].

Loureiro remarks, that he never saw a flower of Oldenlandia with four petals. Other little differences

[e] Linn. suppl. [f] Hort. kew. [g] Linn. spec. [h] Loureiro. [i] Retzius. [k] Forster. [l] Loureiro.

that occur, are perhaps (in his opinion) ſcarcely ſufficient to ſeparate this genus from Hedyotis.]

PROPAGATION AND CULTURE.

Sow the ſeeds early in the ſpring on a hot-bed, and when the plants are come up, tranſplant them to another hot-bed, or into ſmall pots plunged into the bark-bed. Water and ſhade them until they have taken root; then give them free air in warm weather, and frequently refreſh them with water. Some ſeeds will ripen in July, gather them from time to time, as they become ripe; for there will be freſh flowers produced until autumn. Or if the ſeeds be permitted to ſcatter in the pots, the plants will ſoon appear, and will live through the winter in the ſtove, and flower early the following ſpring.

Leaves lanceolate ſerrate, pedunckes lateral aggregate one-flowered.

DESCRIPTIONS, *&c.*

Theſe are evergreen trees. Leaves very ſeldom alternate. Flowers in panicles, axillary or terminating. The firſt ſpecies has one ſeed frequently abortive.[1]

1. α. The wild Olive grows naturally in woods, in the South of France, Spain and Italy, and is therefore not cultivated. The leaves are much ſhorter and ſtiffer than thoſe of the cultivated Olive. The branches are frequently armed with thorns, and the fruit is ſmall and of no value.

[β. Native of the Cape of Good Hope. Given by Thunberg as the common European Olive, of which it is a variety.]

γ. The inhabitants of the South of France chiefly cultivate this, from which they make the beſt oil, a great branch of trade in Provence and Languedoc; the young fruit is alſo the moſt eſteemed when pickled. Of this there are ſeveral varieties.

δ. This is chiefly cultivated in Spain, where the trees grow to a much larger ſize than the preceding; the leaves are much larger, and not ſo white on their under ſide. The fruit is near twice the ſize of the Provence Olive, but of a ſtrong rank flavour, and the oil is too ſtrong for moſt Engliſh palates.

The Olive ſeldom becomes a large tree; but two or three ſtems frequently riſe from the ſame root, from twenty to thirty feet high, putting out branches almoſt their whole length, covered with a gray bark. Leaves ſtiff, about two inches and a half long, and half an inch broad in the middle, gradually diminiſhing to both ends, of a dively green on their upper ſide, and hoary on their under, ſtanding oppoſite. The flowers are produced in ſmall axillary bunches; they are ſmall, white, and have ſhort tubes, ſpreading open at top.

[1] Juſſieu.

[The

[The fruit is a superior berried drupe, of an oblong spheroidal form, and of a yellowish green colour, turning black when ripe: flesh hardish, thick, glaucous: shell bony, ovate-oblong, acuminate at both ends, above at the tip marked with two oblong lateral callufes, the reft of the furface very obfcurely wrinkled; it is thick, and is divided within into two cells; one of them however is very frequently obliterated; one only being fertile, and that lined with a highly polifhed cartilaginous cruft. Receptacle filiform, fpringing from the bottom of the cell, and faftened to the fide of it, reaching upwards to the feed, and inferted a little below the tip into the umbilical fcar. Seed oblong, roundifh, acuminate downwards, pale dun or ftraw-coloured*.

The common mode of making oil from Olives in the kingdom of Naples, is to crufh the fruit to a paffe with a perpendicular mill-ftone, running round a trough. This paffe is put into flat round baskets, made of rufhes, piled one upon another under the preis. After the firft preffure, fcalding water is poured into each baffcet, its contents ftirred up, and the operation repeated till no more oil can be fkimmed off the furface of the tubs beneath. By this method the oil is feldom pure, keeps ill, and foon grows rancid.

Another procefs is recommended, which is performed by pounding the fruit in a mortar. A handful of the crufhed fubftance is thrown into a long woollen bag, which is rubbed very hard upon a floping board, and then wrung; afterwards hot water is added, and it continues to be preffed as long as a drop of oil can be drawn from it. This is fuppofed to have been the original mode of extraction, and if performed by a fkilful ftout workman, to be much more effectual than the common one †.

The Olive, in all ages, has been held in peculiar eftimation, as the bounteous gift of heaven. It is ftill conidered as emblematic of peace and plenty; and the great quantity of oil which it produces in fome countries, effectually realizes the latter of thefe bleffings.

Unripe Olives pickled, efpecially the Provence and Lucca forts, are to many perfons extremely grateful, and are fuppofed to excite appetite and promote digeftion. They are prepared by repeatedly fteeping them in water, to which fome add alkaline falt or quick lime, in order to fhorten the operation; after this they are waffied, and preferved in a pickle of common falt and water, to which an aromatic is fometimes added.

But the principal confumption of Olives is in the preparation of common falad oil. The beft is of a bright pale amber colour, bland to the tafte, and without any fmell. It becomes rancid by age, efpecially if kept in a warm place. It congeals by cold at 38° of Fahrenheit's thermometer, and does not become rancid if kept in a degree of cold equal to the freezing point of water. All the mild expreffed oils of vegetables are nearly of the fame nature; a preference however is generally given to the moft fluid; hence the oils of Olives and Almonds are moft commonly directed for internal ufe in medicine. Oil, in fome fhape, forms a confiderable part of our food, both animal and vegetable, and affords much nourifhment: but with fome oily fubftances do not unite with the contents of the ftomach, efpecially where acids abound. Oil as a medicine is fuppofed to correct acrimony, to lubricate and relax the fibres, and hence is prefcribed in coughs, catarrhal affections and ereufips; in worm cafes, in nephritic pains, fpafms, colics, conftipations of the bowels, &c. Externally it has been found an ufeful application to bites and ftings of poifonous animals, to burns, tumours, &c. both alone and mixed in liniments and poultices.

Oil was much ufed by the ancients to rub over their bodies: this has been found of great fervice in dropfies, particularly in afcites: it is faid to have been fuccefsful even in rabies canina, but having been fince tried in a fimilar cafe without fuccefs, little confidence is to be placed on a folitary inftance. Though the effects of oil taken internally extend over the primæ viæ, yet it may be doubted, whether it produces any medicinal effect after having paffed into the blood.

Oil enters feveral officinal compofitions, and when united with water, by the intervention of alkali, is ufually given in coughs, hoarfenefs, &c.‡

The Olive is commonly fuppofed to be a native of the fouthern countries of Europe: but it feems probable that although it be now found wild in fome parts of our continent, it came originally from Afia. It grows abundantly about Aleppo, mount Lebanon, and many parts of Paleftine. In the northern parts of Africa; and one of the varieties (β) at the Cape of Good Hope.

It appears by the catalogue of the botanic garden at Oxford, that it was cultivated there in 1648*.]

Several Olive trees were planted againft a warm wall at Camden houfe near Kenfington, which fucceeded very well, till their tops advanced above the wall; after which they were generally cut down to the top of the wall in winter. Thefe in 1719 produced a good number of fruit, which grew fo large as to be fit for pickling, but after that time their fruit feldom grew to any fize. With a little protection in fevere froft, the Olive-tree may be maintained againft a wall, in the latitude of London; but in Devonfhire there are fome of thefe trees, which have grown in the open air many years, and are feldom injured by froft, but their fummers are not warm enough to bring the fruit to maturity.

The olive was, by the ancients, confidered as a maritime tree, and they fuppofed it would not thrive at any diftance from the fea; but by experience, we find it will fucceed very well in any country, where the air is of a proper temperature, though it is found to bear the fpray of the fea better than moft other trees.

[The varieties of this tree are numerous, as in moft vegetables that have much attracted the attention of mankind. Several diftinctions from the form of the leaves have been recited in the enumeration of the fpecies: others are taken from the fhape, fize and colour of the fruit.

Virgil enumerates only three varieties—

"Orchites, et radii, et amara pauſia bacca."

The firft bears a fmall round fruit, called Olivola by Cæfalpinus, and Olivaftre by Matthiolus. The Radius is a long Olive, fo called from its fimilitude to a weaver's fhuttle. The Pauſia is called bitter becaufe it was gathered unripe; and then it has a very auftere tafte.

Cato mentions eight, and Columella ten varieties of Olives, among which thefe three of Virgil are enumerated. Many more are recited by Pliny and other authors. It is remarkable that Matthiolus informs us, there were no more than three forts known in his time in Tufcany †.]

In Languedoc they chiefly propagate the Cormean, the Ampoulan, and Mourrau. [In Provence the fmall oblong, the oblong dark green, the fmall roundifh white or Aglandan, the large fleſhy or royal, the large round or Ampoulan, and the fmall round reddifh-black Olive. In Spain they have feveral varieties of their large fruit. In Italy, the fmall Lucca Olive is much eſteemed: and in the fouthern provinces of the kingdom of Naples, where this tree is much cultivated, they have, 1. The Salentine Olive, called by the peafants Ogliarola. 2. Faule, which bears a fmall Olive, kept for eating. 3. Cellina, Scuranefe or Cafcia, yielding leſs oil than the firft in the proportion of two to three; but the tree grows to a greater fize, refifts weather better, and is more fruitful. 4. A Wild fort; the fruit of which grows white as it ripens; the ancients fpeak of fuch a fort; but this is not cultivated ‡.

2. Cape Olive is a fmall tree or rather fhrub, not branching much. Trunk ftraight, with many joints; bark fubaurate, blackifh brown with aſh-coloured dots and lines. Leaves conjugate, decuſſated, fometimes fituated in the end, but commonly entire, denſe and rigid, moderately concave, paler or deeper green, but

* Garner. † Salisburne's travels, 1. 373.

* Woodville. † Hort. kew.

always

always paler underneath, with oblique ſmooth veins, leſs conſpicuous underneath than above. From the axils and at the end of the branches the flowers come out in racemes in june and july, ſometimes thinly diſpoſed, but ſometimes ſo numerous that the racemes hang down. The corolla is white and ſmall.

Native of the Cape of Good Hope[1]. Cultivated 1732 by James Sherard, M. D.[2] Dillenius ſpeaks of the plant at Eltham as being then, ten or eleven years old.

3. Leaves oppoſite, evergreen, petioled, ſhining. Racemes ſhort, axillary, brachiate, with oppoſite pedicels. Segments of the corolla revolute. Style ſo ſhort as to be ſcarcely any. Stigma bifid. Drupe globular, even, handſome. Nut obovate, ſubſtriated, perforated at the baſe. There are male and female flowers on the ſame plant with the hermaphrodites[3].

Native of Carolina and Florida. Cultivated in 1758 by Mr. Miller. It flowers in june[4].

4. Branches round, ſmooth, with an aſh-coloured bark, and raiſed ſcattered dots, compreſſed a little at the top. Leaves oppoſite, coriaceous, broad-lanceolate, attenuated at the baſe, acute, rounded at the tip, frequently emarginate, quite entire, ſmooth, even, veinleſs, an inch and half long, bent back at the edge. Petiole a quarter of an inch long, convex underneath. Racemes a little longer than the petiole, two or three, but ſometimes ſolitary. Pedicels oppoſite. Bracte minute, ovate at the baſe of the pedicels, and two others lanceolate under the calyx. Flowers twice as large as in the common ſort.—Native of Madagaſcar, where it was found by Thouin.

5. Branches round at bottom, with an aſh-coloured dotted bark, alternately compreſſed towards the top. Leaves oppoſite, two inches long and more, ſpreading very much, ſharp at both ends, quite entire, coriaceous, ſmooth, without veins or nerves. Petiole half an inch long. Racemes axillary, oppoſite, ſubſolitary, quite ſimple, a little longer than the petiole. Pedicels oppoſite. Bractes none, except two oppoſite ovate ſcales at the baſe of the common peduncle. Calyx four-cleft, with minute acute ſegments. Filaments very ſhort. Anthers diverging.—Native of New Zealand.

6. Branches round, with an aſh-coloured bark, ſmooth, having raiſed dots ſcattered over them; branchlets alternately compreſſed at top, as in all the ſpecies, with the joints narrower at the baſe, a little dilated above. Leaves oppoſite and alternate, two or three inches in length, or a little longer, an inch and half wide, attenuated to both ends, quite entire, ſmooth, even, coriaceous, veinleſs, paler underneath, obſcurely nerved. Petiole half an inch long, flat above, convex underneath. Racemes axillary, oppoſite, commonly ſolitary, ſeldom in pairs, an inch long, ſimple. Peduncle from a cyathiform bracte, bifid, with divaricated ſegments, like the pedicels, angular. Pedicels oppoſite, one-flowered, the length of the corolla. Bractes oblong, membranaceous, concave, ſometimes villoſe at the edge, the upper ones larger and deciduous, the four loweſt permanent. The flowers twice as large as thoſe of the common Olive. Calyx very ſmall, with very blunt teeth. Corolla four times as large as the calyx, deeply four-cleft. Filaments ſcarcely any. Anthers the length of the corolla. Germ conical, acuminate, ſhorter than the anthers[5].

Native of Madeira, where it was found by Mr. Francis Maſſon. Introduced in 1784[6].

7. This is a large tree. Branches and branchlets trichotomous, obſcurely four-cornered, ſmooth. Leaves deciſſated, oblong, ſharp, a little bent back at the edge, parallel-nerved, reticulated, ſmooth, deep green above, paler underneath, ſpreading, frequent on the branchlets, a finger's length. Petioles ſemicylindric, grooved, ſmooth, a quarter of an inch in length. Flowers on the branchlets, aggregate in umbels, about ſix or eight together, peduncles filiform, one-flowered, ſmooth, half an inch long. Calyx very ſmall, obſcurely four-toothed, whitiſh, ſmooth. Corolla wheel-ſhaped, yellowiſh-white, with ſcarcely any tube, and a ſpreading four-cleft border; the ſegments ovate, blunt, concave, thickiſh. Filaments very ſhort, inſerted into the mouth of the tube: anthers ovate, largiſh, twin[7].

Loureiro, taking this tree to be of a different genus from the Olive, named it *Oſmanthus*, from the remarkable ſweetneſs of the flower. He never could find any fruit, and ſuppoſed the flowers to be always abortive. He deſcribes it as an upright ſhrub, about ſeven feet in height, with aſcending branches, ſometimes climbing. Leaves curved inwards, ſmooth, oppoſite, on ſhort petioles. Flowers pale, ſmall, on ſhort, ſubfaſtigiate, axillary and terminating racemes, on ſhort pedicels. Filaments flat. Anthers lateral, two on each filament. Styles two, thick, awl-ſhaped, embracing the germ with their dilated baſe.

Oſbeck mentions it as one of the ornamental trees in the Chineſe gardens. He ſays it is about ſix yards high, with ſmall, white, ſweet-ſcented flowers, three or four in one involucre.

Native of Cochinchina, China and Japan. It was introduced in 1771, by Benjamin Torin, Eſq. and flowers in july and auguſt[8].]

PROPAGATION AND CULTURE.

In Languedoc and Provence, they propagate the Olive by truncheons, ſplit from the roots of the trees. When their tops are killed by hard froſts in winter, they ſend up ſeveral ſtalks from the root; when theſe are grown pretty ſtrong, they ſeparate them with an axe from the root, in doing which they are careful to preſerve a few roots to them. They are cut off in the ſpring, after the danger of froſt is over, and planted about two feet deep in the ground, covering the ſurface with litter or mulch, to prevent the ſun and wind from penetrating the ground and drying the roots: when the plants have taken new root, they ſtir the ground, and deſtroy the weeds.

In countries where the inhabitants are curious in making oil, they graft their trumcheons with that ſort of Olive which they prefer.

The Olive will grow in almoſt any ſoil, but when it is planted in rich moiſt ground, the tree grows larger and makes a finer appearance than in poor land; but the oil is not ſo good as in a leaner ſoil. Calcareous ground is eſteemed the beſt for theſe trees; the oil being finer and keeping longer than in any other.

[Accordingly we commonly find the Olive in the South of Europe, on white marl or potter's clay, or on limeſtone rock, in mountainous ſituations, unfit for Vines. Virgil's direction correſponds:

> " Difficiles primum terræ, collesque maligni,
> " Tenuis ubi argilla, & dumoſis calculus arvis,
> " Palladia gaudent ſylva vivacis Olivæ
> " Indicio eſt, tractu ſurgens oleaſter eodem
> " Plurimus, et ſtrati baccis ſylveſtribus agri."

Stubborn lands and unkindly hills, where the ſoil is a potter's clay mixed with pebbles, and producing only buſhes, are adapted to the Olive, which is a long-lived ſlow-growing tree. That ſuch lands are congenial to this tree is evident from the abundance of wild Olives that ſpring in them, and the quantity of berries ſtrewed over them. It may be remarked that *Argilla* is not common clay, but white potter's clay; as appears from Columella: " Creta, qua utuntur " figuli, quamque nonnulli *argillam* vocant, inimicif- " ſima eſt viti, nec minus jejuna ſabulo." It may be remarked farther, that *Creta* is never put for chalk, of which there is none in Italy, but for this potter's-clay, or a ſort of white marl.

Virgil, Cato, and Columella recommend the propagation of the Olive by truncheons as the beſt method: and Virgil affirms that even pieces of the trunk will grow. For the culture of Olives, ſee Bernard de l'Olivier. Couture, Traité de l'Olivier, 1786. Duhamel, Traité des Arbres, &c.]

In England the Olive may be propagated by laying down the tender branches (in the manner practiſed for other trees,) which ſhould remain undiſturbed two

[1] Dillenius. [2] Hort. kew. [3] Hort. kew. [4] Vahl. [5] Hort. kew. [6] Thunberg. [7] Linn. mant. [8] Hort. kew.

years;

years; in which time they will have put out roots, and may then be taken off from the old plants, and transplanted either into pots filled with fresh light earth, or into the open ground in a warm situation. The beſt ſeaſon for tranſplanting is the beginning of april, when you ſhould, if poſſible, take the opportunity of a moiſt ſeaſon; and thoſe which are planted in pots, ſhould be placed in a ſhady part of the greenhouſe until they have taken root; but thoſe planted in the ground ſhould have mulch laid about their roots, to prevent the earth from drying too faſt, and now and then refreſhed with water; but you muſt by no means let them have too much moiſture, which will rot the tender fibres of their roots, and deſtroy the trees. When the plants have taken freſh root, thoſe in the pots may be expoſed to the open air, with other hardy exotics, with which they ſhould be hooſed in winter, and treated as Myrtles, and other leſs tender trees and ſhrubs; but thoſe in the open air will require no farther care until the winter following, when you ſhould mulch the ground about their roots, to prevent the froſt from penetrating deep into it; and if the froſt ſhould prove very ſevere, you ſhould cover them with mats, which will defend them from being injured thereby; but you muſt be cautious not to let the mats continue over them after the froſt is paſt, leſt by keeping them too cloſe, their leaves and tender branches ſhould turn mouldy for want of free air; which will be of as bad conſequence to the trees, as if they had been expoſed to the froſt, and many times worſe; for it ſeldom happens, if they have taken much of this mould, or have been long covered, ſo that it has entered the bark, that they are ever recoverable again; whereas it often happens, that the froſt only deſtroys the tender ſhoots, but the body and larger branches remaining unhurt, put out again the ſucceeding ſpring.

Theſe trees are generally brought over from Italy every ſpring, by the perſons who import Orange-trees, Jaſmines, &c. from whom they may be procured pretty reaſonable; which is a better method than to raiſe them from layers in this country, that being too tedious; and thoſe which are thus brought over, have many times very large ſtems, to which ſize young plants in this country would not arrive in ten or twelve years. When you firſt procure theſe ſtems, you ſhould (after having ſoaked their roots twenty four hours in water, and cleaned them from the filth they have contracted in their paſſage) plant them in pots filled with freſh light ſandy earth, and plunge them into a moderate hot-bed, obſerving to ſcreen them from the violence of the ſun in the heat of the day, and alſo to refreſh them with water, as you ſhall find the earth in the pots dry. In this ſituation they will begin to ſhoot in ſix weeks or two months after, when you ſhould let them have air in proportion to the warmth of the ſeaſon; and after they have made pretty good ſhoots, you ſhould inure them to the open air by degrees, into which they ſhould be removed, placing them in a ſituation where they may be defended from ſtrong winds; in this place they ſhould remain till October following, when they muſt be removed into the green-houſe, as was before directed. Having thus managed theſe plants until they have acquired ſtrong roots, and made tolerable good heads, you may draw them out of the pots, preſerving the earth to their roots, and plant them in the open air in a warm ſituation, where you muſt manage them as was before directed for the young ones; and theſe will in two or three years produce flowers, and in very warm ſeaſons ſome fruit, provided they do well. The Laurea and Box-leaved Olives are the hardieſt, for which reaſon they ſhould be preferred to plant in the open air, but the firſt ſort will grow to be the largeſt trees.

[Olea fragrans may be increaſed from cuttings, in the ſame manner as Gardenia.

OLYRA. (Olyra of Homer, Herodotus, Hippocrates, Dioſcorides, &c.)

Lin. gen. n. 1045. *Reich. n.* 1136. *Schreb. n.* 1406. *Juſſ.* 33. *Swartz obſ.* 347.

Claſſ. 21. 3. Monoecia Triandria.

Nat. order of *Gramina*, *Graminea* or *Graſſes*.

GENERIC CHARACTER.

* *Male* Flowers, below the females.

Cal. *Glume* two-valved, one-flowered: *valves* equal, lanceolate: *outer* ſubventricoſe, terminating in a capillary, ſtraight, even *awn*; *inner* narrower, acute, folded in on both ſides.

Cor. none.

Nectary two-leaved, very ſmall: *leaflets* obovate, ſubemarginate, membranaceous, erect.

Stam. *Filaments* three, capillary, very ſhort. *Anthers* linear, acute at both ends.

* *Females* ſolitary, terminating on the ſame panicle, much larger than the males.

Cal. *Glume* two-valved, one-flowered, large, ſpreading: *valves* almoſt equal, ovate, concave, nerved: *outer* terminating in a long, awl-ſhaped, ſubflexuoſe *awn* villoſe at *bottom*: *inner* narrower, acuminate.

Cor. *Glume* two-valved, much ſhorter than the calyx, coriaceous, ſhining, awnleſs, blunt: *outer* much longer.

Nectary three-leaved, very ſmall: leaflets obovate, membranaceous, erect.

Pist. *Germ* oblong. *Style* filiform, almoſt the length of the calyx. *Stigma* capillary, pubeſcent.

Per. *Glume* of the corolla involving, filling.

Seed ovate.

ESSENTIAL CHARACTER.

Male. *Cal.* Glume one-flowered, awned. *Cor.* glume awnleſs, (*Cor.* none. *Sw.*)

Fem. *Cal.* Glume one-flowered, ſpreading, ovate. *Style* bifid. *Seed* cartilaginous.

SPECIES.

Panicle terminating, culm branched.

2. Olyra paniciflora.

Swartz prodr. 21. *ſuppl.* 125. *Leſſ. it.* 243. 100.

Flowers axillary.

DESCRIPTIONS, &c.

1. Roots fibrous, long, thicker. Culm erect, a fathom high, jointed, round, branched at bottom. Joints ſimple. Leaves ſheathing, as it were ſhortly petioled at the end of the ſheath, broad-lanceolate, acuminate, horizontal, ſpreading, ſmooth, ſtriated, marked with lines below. Sheaths pubeſcent. Panicle terminating, erect, ſpreading, many-flowered. Branches angular, rugged, flexuoſe. Male ſpikelets numerous, preſſed cloſe to the branches of the panicle, alternate, pedicelled, three commonly contiguous. Pedicels flexuoſe, filiform, ſhort. Female flowers ſolitary, terminating the male ſpikes, and three times the ſize of the males.

Native of Jamaica, in dry coppices; flowering from january to july [1]. Introduced in 1783, by Mr. William Forſyth [2].

2. This alſo is a native of Jamaica [1]. Loureiro has a third ſpecies, which he names O. orientalis.

[1] Swartz. [2] Hort. kew. Swartz.

GENERIC CHARACTER.

* *Male* flowers.

CAL. *Perianth* four or five-leaved, spreading: *leaflets* two opposite larger, ovate, convex, coloured.

COR. none.

Nectary. Glands four, or a fleshy ring encircling the germ.

STAM. *Filament* one, columnar, thick, short. *Anthers* two, oblong, incumbent, connate at top, pollniferous at the edge: or one, plano-convex, trifid.

* *Female* flowers, in the same raceme.

CAL. *Perianth* five-leaved: *leaflets* three larger, ovate, encircling the germ.

COR. none.

PIST. *Germ* ovate. *Style* none. *Stigma* trifid.

PER. *Capsule* oblong or roundish, fleshy, bluntly triangular, three-celled, three valved.

SEEDS. *Nuts* solitary, ovate, hard.

ESSENTIAL CHARACTER.

MALE. *Cal.* four-leaved. *Cor.* none. *Filam.* columnar, with the anthers inserted into it.

FEM. *Cal.* five-leaved. *Cor.* none. *Stigma* trifid. *Capf.* fleshy, three-celled. *Nuts* solitary.

SPECIES.

1. Omphalea axillaris.
Swartz prodr. 95.
Racemes axillary, leaves distich ovate acuminate shining, on very short petioles, stipules mucronate, stem shrubby.

2. Omphalea caulifiora.
Swartz prodr. 95.
Racemes cauline scaly at the base, leaves distich oblong acute shining, stem arborescent.

3 Omphalea cordata.
Swartz prodr. 95. *obf.* 350.
O. diandra. *Lin. fpec.* 1377. *Reich.* 4. 118. *Brown. jam.* 334. *Aubl. guian.* 843. *t.* 328.
Racemes compound leafy terminating, leaves scattered cordate villose underneath, biglandular at the base, stem scandent.

4. Omphalea nucifera.
Swartz prodr. 95. *obf.* 351.
O. triandra. *Lin. fpec.* 1377. *Reich.* 4. 118. *amoen.* 5. 408. *Brown. jam.* 335. fed non *t.* 22. *f.* 4. (Sw.)
Racemes compound leafy terminating, leaves scattered oblong very smooth biglandular at the base, stem arborcous.

DESCRIPTIONS, *&c.*

1, 2. Natives of Jamaica.

3. Stems shrubby, scandent, subdivided, diverging, round, pubescent. Leaves alternate, acuminate, subcoriaceous, thick, entire, smooth, pubescent underneath; on longish, loose, biglandular petioles: glands depressed, roundish. Stipules at the base of the leaves, small, lanceolate, deciduous. Racemes branched, diverging, loose. Bractes lanceolate, pedicelled, obtuse, smooth, at the base of the racemelets; which are many-flowered; the flowers in clusters, peduncled, small, green. Calyx four-parted, with roundish segments, two of which are larger. Filament from the centre of a coloured concave disk, convex at top; anthers purple, inserted into the margin of the filament. Germ roundish, three-cornered. Style very short, fleshy, three-cornered. Stigma trifid, villose. Capsule large, yellowish, containing three brittle nuts, with oblong, angular kernels.

Native of rocky coppices in Jamaica, and other parts of the West Indies.

4. This is a small tree, with an upright even trunk, from twelve to fifteen feet high: the branches spreading horizontally, bent down, warted, subdivided, elliptic-elongated, alternate, scattered, a foot and half long, nodding, attenuated at the base, blunt at top, entire, very smooth, nerved. Petioles bent down, long, roundish, smooth. Glands in pairs, flat, depressed, round, perforated in the middle, distilling moisture. Racemes solitary, the length of the leaves, nodding, loose. Bractes petioled, subaxillary, oblong, entire, biglandular at the base. Racemelets alternate, divaricating, with two or three male flowers on a pedicel, and one female in the middle of each. Calyx five-leaved, three of the leaflets larger, ovate, convex, membranaceous at the edge, coloured. Nectary a fleshy, blood-red ring. Filament purple, from the middle of the disk. Anther plano-convex, purple, trifid, with three pollniferous incisures. Germ oblong, three-cornered, striated with six lines. Stigma perforated. Capsule pendulous large, roundish, obtusely three-cornered, containing three very hard, black, oblong nuts, with a whitish kernel in each surrounded by a yellow membrane. Cotyledons two-leaved, compressed, veined, the length of the kernel.

Native of Jamaica, where it is frequently cultivated. It is called by the English Cobnut, by the French Noisettier. The kernels are esculent and sapid, the cotyledons only being emetic. The branches and petioles on being broken pour out a tenacious watery liquor[a].

Cultivated in 1763, by Mr. Miller. It flowers in june and july[b].]

Filix indica, polypodii facie. *Mentz. pug.* 6. *t.* 10.—Osmundæ facie. *Bed. à Stapel.* 320.
Polypodium virginianum majus, Osmundæ facie, tenerum. *Mor. bifl.* 3. 563. *f.* 14. *t.* 2. *f.* 10.
Fronds pinnate, fubracemofe at the tip.

2. Onoclea polypodioides.
Lin. fyft. 926. *Reich.* 4. 376. *mant.* 506.
Fronds bipinnate, fructifications three-valved.

DESCRIPTIONS, *&c.*

1. Fronds thin, pale green, even; the divisions oppofite, wide, finuate, fo very tender, that on being touched or ever fo little compreffed, they wither and perifh[c].

Native of Virginia. Cultivated in 1758, by Mr. Miller[d]. It muft have been many years before in the Oxford garden, fince in the third volume of the Hiftoria Oxonienfis (1699) it is faid, that they had not been able to remark the fructification, though they had received it feveral years fince from Virginia, and had cultivated it.

2. Root creeping, fibform, fhining, rufous. Frond compound. Leaflets bipinnate, oppofite, fpreading. Pinnas fuboppofite, remote, linear, pinnatifid to the very midrib, blunt ish. Fructifications as in Polypodium, marginal towards the base of the toothlets, thin, flattifh, covered. Calyx three-valved, or membranaceous three-parted, cloven from the centre towards the base.

Obf. Fructifications rounded, covered with a membranaceous three-valved lid, fixed at the edge, feem rather to indicate this to be an Onoclea than of any other genus; although the other fpecies has pinnate leaves fomewhat racemofe at top.

Native of the Cape of Good Hope, in fiffures of the rocks near the top of the Table Mountain; where it was found by Koenig[e].]

DESCRIP-

DESCRIPTIONS, &c.

[These are herbaceous plants or undershrubs. Leaves ternate, with the leaflets often serrulate. Stipules fastened to the bottom of the petiole. Flowers yellow or purple, axillary or terminating, sessile or more frequently peduncled, the peduncles sometimes awned, sometimes not, one or many-flowered. Legume in some oblong, in others very short, nearly equal to the calyx, containing one or two seeds[1].—N. 7. 8, 9, 10, 11, 12, 19, 21, 25, are annual; the others are perennial or shrubby.

1. Root perennial. Stems straight, hard, smooth and almost woody. Flowers purple. The leaves are smaller and less villose than those of the next species, of which perhaps it is no more than a variety[2]. According to Linneus, it is shorter, stiffer, more thorny, almost smooth; with solitary peduncles, twice as long as the bracte.

Native of the South of Europe, as Dauphiné, the county of Nice, &c. in meadows and pastures.

2. In our common thorny Rest-harrow, at the base of the branches are strong thorns, and the branches themselves terminate in soft thorns. Stem slightly hairy. Leaves almost smooth. Calyx hairy, with five awl-shaped unequal segments. Flowers twice as long as the calyx. The whole plant is more rigid and woody, than our thornless Rest-harrow[3]; for which, in its young state, before the thorns are formed, it has frequently been mistaken. The corolla is red[4].]

It has a strong creeping root, which spreads far in the ground, and is with great difficulty eradicated, hence its names of *Resta bovis* and *Arrete boeuf*. Stems a foot and half high, slender, purple, hairy, sending out many lateral branches, armed with sharp prickles. The flowers come out singly from the side of the branches, they are of a bright purple colour marked with lines, and are succeeded by small pods, containing one or two kidney-shaped seeds. [Four or five, according to Gaertner, shagreened with very minute dots.

It is thus described by Retzius:—stems decumbent, villose, red, thorny especially from the base to the middle. Thorns two inches long, awl-shaped, pungent, sometimes but seldom furnished with a small leaf or two. Leaves and petioles smaller than in his *arvensis*, which is our *hircina*, obovate, hairy on both sides, and not serrated along the whole circumference. Flowers remote, at the distance of one or two inches, and therefore scarcely racemed, commonly solitary, but if there be two together they are on a common bird peduncle. The corolla has the banner by no means emarginate, but furnished with a soft awl-shaped little point: keel more gaping underneath somewhat longer than the wings. The plant, except in length, is less than *hirsuta*, more woody, and of a darker colour.

Monsr. Villars does not distinguish our *arvensis* from this. He says that it has no spines whilst it is young, but acquires them with age, and that they become stronger as the plant grows older, especially in poor land. It is a little villose and viscid when young, or in strong land, but loses part of its down and all its clamminess in low poor wet grounds: it then approaches to the first sort. It varies with white flowers, but this variety differs no otherwise from the common sort. All the varieties have ternate leaves; the leaflets are oblong, elliptic, sharply toothed; the branches do not acquire thorns till the second or third year, the flowers form a spike in the young plant, and become axillary or lateral when it is older. Loeselius long since and Haller affirmed that the young plant of Rest-harrow is smooth, and acquires thorns with age. —See what is said on the next sort.

Native of Europe, chiefly in barren pastures, both in a sandy and strong soil. Flowering the greater part of the summer from June.

It is named in English *Thorny Rest-harrow*, *Cammock*, *Petty Whin*, *Ground Furze*, in Yorkshire *Rustburn*, perhaps corruptly from Rest-bourn. Gerarde says, the root is long and runneth far abroad, very tough and hard to be torn in pieces with the plough, insomuch that the oxen can hardly pass forward, whereupon it was called Rest Plough or Rest Harrow. I am at a loss to conceive how the latter name prevailed, since that implies a superficial impediment, whereas it proceeds from the roots. This quality of the plant makes it very fit to be sown on sea and fen banks.

A decoction of these roots has been recommended in cases of jaundice. Kine and goats eat it; sheep are fond of it; horses and swine refuse it[5]. Dr. Stokes says, that a horse refused the whole branch, but eat of the younger shoots when picked off.

Mr. Woodward remarks of the figure in the Flora Danica, that the leaves are too pointed, and too deeply serrated, and that spines are represented at the ends of the branches only.

3. Our hairy or thornless Rest-harrow has the stem, branches and leaves soft and whitish with down. Flowers numerous, mostly solitary, alternate on the young shoots: corolla but little longer than the calyx; the segments of which are more tapering than in *O. spinosa*[6].—This is a smaller plant than that. Stems and branches woody, cylindrical, a little hairy. Leaves set with glandular hairs; the upper oblong-ovate, toothed. Petioles short, fixed to a broad toothed stipule. Flowers scattered, intermixed with leaves. Calyx, some of the hairs long and tapering, others short and tipped with glands; segments, four of them pressing on the standard, the lowermost supporting the keel. Standard of the corolla circular, with a small point at the end, with short hairs on the outside, of a fine rose-colour, streaked with deeper coloured lines; wings more than half as long as the standard, ovate, white; keel coloured and streaked as the standard. Germ with hairs tipped with glands. Seeds about six. Flowers sometimes nearly white. The hairiness of the leaves, and the want of thorns, best distinguish this from *O. spinosa*, the leaves of which are scarcely, if at all hairy on the upper surface, though in both they are edged with hair-like glands terminating in a small globule[7].

Linneus and others suppose this to be a mere variety of the thorny Rest-harrow, or the same plant in the younger period of its life.] Mr. Miller affirms that he has cultivated both by seeds, and has always found the plants retain their difference; that the stalks of this are hairy and more diffused than those of the *spinosa*; the leaves broader and sitting closer on the branches; the stalks not so upright and without spines.

[Mr. Woodward relates, that in the autumn of 1779, he examined many hundred plants in the cornfields about Berkhamstead in Hertfordshire, without meeting with a single one thorny; whereas in the neighbourhood of Bungay he never met with one without spines in any part of the year. Dr. Withering also informs us that Mr. Pitt of Pendeford near Wolverhampton sent him specimens which never became thorny, and that the thorny sort is never found in that neighbourhood: and that he found it in great plenty on St. Vincent's rocks, without the least appearance of thorns on any of the plants, though he examined a great number. These accounts agree entirely with my experience. In the part of the country where I live, in the counties of Bedford and Huntingdon, the Ononis has never occurred to me without thorns. It is found in pastures and the borders of corn fields, chiefly in light lands. The arvensis of many places on the continent is the fifth species, which is not found wild in England. It varies with white flowers as well as the foregoing sort.

β. A variety of *O. arvensis* has been found on our sea coasts in Cornwal, near Deal in Kent and Yarmouth in Norfolk; also by Charlton Church, Woolwich, and Gravesend. At Sandscale, and in Walney, in Low Furness, &c. This was supposed to be the same with *O. repens* of Linneus, but according to Mr. Afzelius that species has not been found in England. Mr. Hudson cultivated both our plants four years, and could not discover any specific difference. Both, according to him, are villose and somewhat clammy, with the flowers solitary, or two together, sometimes

[1] Jussieu. [2] Villars. [3] Woodw. Mss. [4] Withering. [5] Linn. [6] Woodw. Mss. [7] Withering.

three. Mr. Woodward says it is not so downy as the arvenſis, that the flowers are larger and fewer, the ſegments of the calyx ſhorter and blunter, the leaves longer, broader at the extremity, and more tapering at the baſe (oblong wedge-ſhaped.) Removed into a garden it grows upright, and is more downy.

4. This is very nearly allied to the preceding, but differs in having the ſtems procumbent diffuſed every way, and in being ſmaller. Flowers ſolitary from the axils.

Native of the Levant[a], but not of England, as Linnæus ſuppoſed it to be. Perhaps it may not be really different from the preceding. The ſpecies ſeem to have been too much multiplied.

5. This has never any thorns. The branches and eſpecially the calyx are very villoſe. Leaves ſoft, finely hairy. Flowers terminating in a ſpike, two together, pedunculed. Standard reflex, almoſt flat; keel bent in at an obtuſe angle. Fruit ſhorter than the calyx, very hirſute. In the common Reſt-harrow the ſtipules are much ſmaller, hooked; the fruit leſs hirſute, longer than the calyx; the keel of the flower bent in at a right angle. Flowers ſolitary[b].

Retzius thus deſcribes his arvenſis, which is this ſpecies.—Stems almoſt upright, villoſe, green, viſcid, twice as thick as thoſe of the thorny Reſt-harrow, without any thorns. Leaves ſimple and ternate, ovate, ſerrate all round, naked underneath, above villoſe, with hairs having a globular gland at top. Petioles winged, ſtipule-ſhaped, with large, ſerrate, almoſt embracing wings. Flowers almoſt twice as large as thoſe of thorny Reſt-harrow, in a terminating raceme, commonly two together: both peduncles from the ſame point. Calyx villoſe, five-cleft, with linear, acuminate, ſtriated teeth, the two uppermoſt of which follow the back of the ſtandard; the two middle ones lie over the edges of the ſtandard, and the fifth covers the opening of the keel at bottom. Standard a little emarginate. Wings the length of the keel. The whole plant is larger than that of ſpinoſa, more ſucculent, paler, and has a goatiſh ſmell. It neither has thorns nor creeps. Cluſius ſays, that this goatiſh ſmell reſembles that of Fraxinella, than which nothing ſeems to me more different. In Ray's ſynopſis it is ſaid of our common thornleſs Reſt-harrow, *hircum olet hæc planta*.

Native of Sweden, Germany, Italy and Hungary. Introduced in 1774, by Joſeph Nicholas de Jacquin, M. D. It flowers from may to auguſt[c].

This ſpecies ſeems to be ſtronger than our common Reſt-harrow, and together with the Natrix and viſcoſa, is recommended by ſome, foreign phyſicians as a powerful diuretic, and ſerviceable for cleanſing the urinary paſſages, and in an incipient dropſy. The bark of the root is the moſt efficacious part of the plant.

6. Stem herbaceous, round, decumbent, ſubdichotomous. Branches ſlender. Lower leaves ternate, upper ſimple, at the tops of the branches scarcely any, all petioled. Leaflets wedge-form-linear, ſerrate-toothed with three teeth on each ſide, at top tranſverſe, three-toothed ſeldom five-toothed, a quarter of an inch in length; the lateral ones ſmaller. Petiole the length of the leaves. Stipules faſtened on each ſide to the petiole, and only half its length, ovate-lanceolate, ſtriated, toothletted. Flowers axillary, ſolitary, ſubſeſſile, the lower ones more remote, the uppermoſt ſupported by a ſtipule at the baſe. Calyx five-toothed, ſtriated, with lanceolate-linear ſegments, the length of the corolla. Legume villoſe, oblong, four-ſeeded, the length of the calyx'.]

7. This is an annual plant, about nine inches high, ſending out one or two ſide branches towards the bottom. Leaves ſmall, ovate, indented on their edges, and ſtanding upon pretty long foot-ſtalks. Flowers axillary, ſolitary, ſmall, yellow, ſeſſile, with a ſharp briſtly bracte. Pods very ſhort, turgid; containing two or three kidney-ſhaped ſeeds.

[Stems filiform, diffuſed, ſmooth, ſufrutticoſe. Stipules very much acuminated, ſubbipartite, quite entire. Leaflets ſomewhat oblong and rigid, ſerrate, recurved, ſcarcely mucronate. Petioles very ſhort. Flowers axillary, ſolitary. Calyxes ſmooth, deeply five-cleft, ſtraight, awl-ſhaped. Corolla yellow. Legume ovate, brown, ſhorter than the calyx. Upper floral leaves ſimple[e].

Villars remarks, that the ſtems are many, ſimple, from ſix to eight inches in height; leaves ternate, on a petiole ſupported by two ſtipules, lengthened out into an awn, and entire; leaflets ſmooth, very dark green, oblong a little enlarged at the ends, with ſharp teeth, not very deep. Flowers on the upper part of the ſtem and branches, yellow, ſmall, axillary, ſolitary. The leaves which ſupport theſe are often ſimple. Calyx cut to the baſe, briſtle-ſhaped, longer than the flower and fruit. Legume oval, blackiſh, ſmooth.

Native of the South of Europe. Cultivated in 1739, by Mr. Miller. It flowers in june and july[f].]

8. Stem upright, a foot and half high, ſending out ſmall ſide branches. Leaflets roundiſh, ſerrate, on ſhort foot-ſtalks. Flowers in ſhort leafy ſpikes at the ends of the branches; they are ſmall, and of a pale purple colour. Pods ſhort, turgid, containing two or three kidney-ſhaped ſeeds.

[According to Linnæus, the ſtem-leaves are ternate; the floral leaves ſimple. Stipules and bractes embracing, membranaceous-cartilaginous, even, ovate, concave, among the flowers imbricate in a ſpike, covering the calyxes. Calycine ſegments ovate, bent back at the ſides, having viſcid briſtles ſcattered over the inſide, as the legume has alſo.

Dillenius ſays that it is a mean between the upright and procumbent ſpecies, the principal ſtem being upright, from a foot to two feet in height, the other ſtems and branches procumbent; they are round and hairy; the ſhoots terminate in ſpikes of flowers from half an inch to an inch in length. Corolla ſmall, pale purple. It has no ſpines, it is not clammy, and it has not any ill ſmell.

Native of Spain and Portugal. Cultivated in 1732, by James Sherard, M. D.[g]]

9. This is an annual plant, riſing with upright branching ſtalks a foot high. Leaves ſingle, ſeſſile; the larger leaves oval, about an inch long, and three quarters of an inch broad; the upper leaves narrow, ending in obtuſe points, and ſlightly indented at their ends. Flowers in leafy ſpikes at the ends of the ſtalks ſet cloſe together, having hairy calyxes; they are pretty large, of a purple colour, and appear in july. Pods taper, about an inch long, incloſing four or five kidney-ſhaped ſeeds.

[Native of Spain and Portugal. Cultivated in 1696, by Mr. Jacob Bobart[h].

10. This has the appearance of an Euphraſia, branched, diffuſed, viſcid-pubeſcent. Stipules cordate, very wide, plaited, toothed, emarginate, wider than the leaves. Leaves ſimple, wedge-form-obovate, plaited, finely toothletted. Flowers axillary, ſolitary, ſubpeduncled. Calyxes ſhorter than the corolla[i].

Native of the South of Europe, on the ſea coaſt, as in Italy, and in Sicily very abundant. Annual.

11. Stem a foot high, diffuſed, round, a little flexuoſe at bottom, hairy-ſubviſcid, branched. Branches of the ſame ſtructure with the ſtem, quite ſimple, the lower ones procumbent, the upper ones ſpreading. Leaves alternate, half an inch long, remote, ſpreading, oblong, finely ſerrulate: floral leaves pubeſcent, of the ſame form with the ſtem-leaves, but ſmaller. Stipules the length of the petiole, narrower by half than the leaves, quite entire at bottom, finely ſerrate at top. Flowers from the upper axils, at firſt cloſe together in a ſhort ſpike, afterwards remote, on ſhort peduncles, ſolitary. Pedicels the length of the petiole. Bractes none. Calyx five-cleft, hairy viſcid; ſegments lanceolate, ciliate, the loweſt twice as broad as the reſt. Corolla the length of the calyx, pale red.

[a] Linn. [b] Allione. [c] Hort. kew. [d] Vahl. [e] Linn. ſyſt. [f] Hort. kew. [g] Idem. [h] Idem. [i] Linn. ſpec.

It is a mean between O. alopecuroides and pubescens. From the former it differs in its ferrate ſtipules, the floral leaves of the ſame ſtructure with the ſtem-leaves only ſmaller, not linear and narrower towards the baſe: from the latter, in having all the leaves ſimple, and the ſtipules ferrate [m].

Native of Barbary, on the ſea-ſhore, flowering in the month of june. The whole plant is covered with a ſlight down except the leaves, and it is a little viſcid [n].

12. Stems a foot high, branched, diffuſed, round. The whole plant pubeſcent-viſcid. The ends of the branches heaped with leaves and flowers, which gradually become more remote. Lower leaves ternate, the reſt ſimple. [o] Leaflets ovate or oval, obtuſe, acutely ſerrate. Stipules ovate-lanceolate, faſtened to a petiole of the ſame length, quite entire. Petioles the length of the leaves. Peduncles axillary, awnleſs, the length of the petioles. Calyxes lanceolate, bluntiſh, the length of the corolla [p].

Native of the South of Europe. Gouan had the ſeeds from Majorca or Minorca. Annual. Introduced in 1783, by Monſ. Thouin. It flowers in auguſt [q].

13. This is a ſhrub, having the appearance of Geniſta canarienſis. Branches round, purple, with whitiſh hairs ſcattered over them. Leaves ternate, petioled, ſmall, purpliſh underneath: leaflets ſeſſile, ſomewhat wedge-ſhaped, blunt, ſcarcely emarginate. Racemes erect, hairy, as are alſo the calyxes. Corollas ſmall, yellow. Stamens connate, with a cleft above. Legume linear, drooping, ſickled backwards, compreſſed toruloſe [r].

Linnæus firſt named it Cytiſus æthiopicus, under which name Mr. Miller deſcribes it thus.] Stalk ſoft, ſhrubby, eight or ten feet high, putting out many ſlender branches on every ſide. Leaves ſmall, wedge-ſhaped, indented at the top, dark green, ſmooth. Flowers frequently ſingle from the ſide of the branches, large and of a bright yellow. He ſays that it grows naturally about Algiers whence Dr. Shaw brought the ſeeds, which ſucceeded in the Cheliea garden.

[Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers from july to ſeptember.

14. This alſo is a native of the Cape, and was introduced by Maſſon in 1787 [s].

15. Stems a foot high, branched, rod-like, numerous, proſtrate, filiform. Leaflets ſeſſile, obcordate or obovate, obtuſe, naked. Petioles the length of the leaves, ſcarcely pubeſcent. Stipules minute, lanceolate. Flowers in umbels about five together (four to eight); ſometimes but ſeldom two flowers under the umbel, without any evident involucre. Common peduncles axillary and terminating, very long, filiform. Calyxes pubeſcent. Filaments connate. Legume with the dorſal ſuture rugged.

Native of the Cape of Good Hope [t].

16. This reſembles a Glycine, but has not the character. It was found at the Cape by Thunberg.

17. In appearance it agrees with O. umbellata. This alſo was found at the Cape by Thunberg [u].

18. This has the ſtature of Lotus corniculata. Root ſimple, deſcending. Stems numerous, branched, hardiſh, filiform, diffuſed, a ſpan high. Leaves ſubſeſſile. Leaflets ovate, mucronate, ſmall, ſubpubeſcent. Stipules none. Peduncles axillary, filiform, much longer than the leaves, ſubtriflorous at top: flowers alternate, pedicelled. Legume cylindric, acute.—Native of the Cape [v].

19. Herbaceous, pubeſcent. Stipules ſubcordate. Petioles longer than the leaflets, which are mucronate, the middle one on a longer petiole, and more retuſe. Racemes axillary, ſolitary, ſimple, twice as long as the leaves, compoſed of about ſix alternate flowers. Corolla yellow and violet purple. It is an annual plant, and native of the Cape [w].

20. Stems numerous, a ſpan long, filiform, weak, herbaceous. Leaves petioled, lanceolate, mucronate at both ends, ſmooth, pubeſcent underneath. Stipules very minute, acuminate. Peduncles filiform, jointed below the top. Calyx the ſize of the leaves. Legume ſubtomentoſe, mucronate, horizontal, twice as long as the calyx. This is believed to this genus, appears from the coaleſcent filaments [x]. Linnæus had firſt ranged it with Lotus. Native of the Cape.

21. This is an annual plant, pubeſcent viſcid, ſmall, diffuſed, ſpreading. Leaves petioled, orbiculate, thickiſh, plaited, pubeſcent-viſcid. Stipules oval, ſpreading, blunt, ſerrate. Peduncles axillary, ſcarcely the length of the leaves. Calyxes the length of the peduncle, blunt. Corollas white with the ſtandard purple underneath. Calyx after flowering bent back at top to the ſtem. Legume half as long again as the calyx, villoſe, cloſely bent back under the peduncle, brown. Native of Spain and Italy [y].

22. Stems a finger's length, ſomewhat branched, even. Leaflets even, rounded at the top, ſharply and very finely-ſerrate. Stipules lanceolate. Peduncles lateral, much longer than the leaves. Calyx ſhort, even. Standard purple, ſtriated [z].

It is ſmall, though woody; entirely ſmooth except the calyx. Stems thin and hard. At the baſe of the leaflets are two green pointed lanceolate toothed ſtipules. Leaflets oblong, ſharply toothed. Flowers large in proportion to the plant, growing one by one from the axils of the upper leaves, on a peduncle about an inch in length. Standard rounded, bent back at top, purple with darker red veins; wings and keel much ſhorter, white. Capſule ſmooth, ſhort, ſwelling [a].

Native of Italy, at the foot of mont Cenis, &c. and of Dauphiné. Villars is of opinion that Linnæus intended this plant, when he ſpeaks of the reclinata as a native of Dauphiné; and Allione ſuppoſes the reclinata of Linnæus to belong to this ſpecies. He ſays, that it varies with ſmooth and hairy leaves; with the flowers cloſe on ſhort peduncles, and remote on long peduncles. The whole plant is ſometimes covered with flowers, and ſometimes they are only at the ends of the branches.

Mr. Miller deſcribes it under the name of Ononis criſtata. He therefore cultivated it before 1759. According to the Kew catalogue it was introduced in 1778, *by Monſ. Thouin.*

23. Viſcid-villoſe, with a woody ſtem. Leaflets wedge-form, ſtriated, toothed, towards the baſe quite entire, the lateral ones ſmaller. Stipules cowled, covering the whole ſtem, oblique to the ſtem, bifid on the outſide, ſtriated, the lower ones dry. Peduncles alternate, from the middle to the end of the ſtem, ſolitary, awned a little below the calyx with a linear leaflet the length of the calyx, erect, an inch in length. Calyx ſtriated, with lanceolate ſegments, ſhorter than the corolla. Corolla yellow, with a purple-ſtriated ſtandard. Legume bent back. At one time of the year it puts on an appearance ſo different as to be eaſily taken for a diſtinct ſpecies: with the branchlets cluſtered, half an inch long, leaflets and the ſtipules ſmaller cloſely imbricate [b].

24. Allied to O. minutiſſima, but the leaves viſcid-villoſe underneath, and not ſmooth. Stipules diverging, ſerrate, lanceolate at the top, not ſheathing, quite entire or ſetaceous. Calyxes pubeſcent, the length of the corolla; not ſmooth and longer than the corolla [c].

Root woody. Stem procumbent, diffuſed, wrapped in ſtipules every way. Leaves ſubſeſſile, toothed at top. Stipules lanceolate, ſharp, ſerrate. Peduncles axillary, longer than the ſtem, villoſe and viſcid, terminated by a very ſhort truncated thread, coming out below the flower. Calyx five-cleft, villoſe and viſcid, with lanceolate-linear, acute, long ſegments. Standard large. Legume ovate, flat, nodding. Flowering peduncles erect; fruiting peduncles nodding.

Native of the South of Europe, introduced in 1771, by Monſ. Richard. It flowers in june and july [d].

25. This is an annual plant, with a ſtrong herbaceous hairy ſtalk, a foot and half high, ſending out branches the whole length. The middle leaflet is

[m] Vahl. [n] Poiret. [o] Linn. mant. [p] Hort. kew. [q] Linn. ſyſt. [r] Hort. kew. [s] Linn. mant. [t] Linn. ſuppl. [u] Linn. mant. [v] Linn. amœn. [w] Vahl. [x] Linn. ſpec. and ſyſt. [y] Linn. mant. [z] Villars. [a] Vahl. [b] Linn. ſpec. [c] Gou. prop. [d] Hort. kew.

large and oval, the ſide ones are long and narrow, rounded at their points, indented on their edges, and very clammy. Peduncles axillary, ſolitary, each ſuſtaining one pale-yellow flower, ſtanding erect in the middle of the peduncle.

[The whole plant is beſet with glutinous hairs. Stem angular, branched. Leaves on the ſtem often ternate, ſubferrate; on the branches ſimple. Stipules embracing, bifid. Peduncles terminated by a briſtle longer than the flower. Calyx deeply cut into linear ſegments. Legume ovate, turgid, nodding, longer than the calyx[f].

Native of the South of France and Spain. Cultivated by Mr. Miller in 1768[g].] He ſays that the ſeeds were ſent him from Portugal, where it grows naturally.

[8. Is larger, and the calyxes are longer than the corolla[h].

26. Stem erect, flexuoſe, with ſhort alternate branches. Leaves on oblong petioles, viſcid: leaflets obovate, ſerrate, the middle one double the ſize of the two others. Stipules ſemi-cordate. Peduncles longer than the petiole. Calycine leaflets filiform. Legumes compreſſed, toruloſe[i].]

Annual; nine inches high, with one or two branches towards the bottom. Leaves ſmall, on ſhort foot-ſtalks, each ſuſtaining two ſmall yellow flowers. Pods jointed, compreſſed like thoſe of Bird's-foot, having four or five ſeeds. It flowers in July, and the ſeeds ripen in the autumn.

Native of Sicily, [at Capo Paſſaro. Cultivated by Mr. Miller in 1759.

27. This reſembles O. Natrix very much, but the ſtem is more ſucculent and more angular; the leaves larger, lanceolate-oblong; the awns of the peduncles the length of the flower, ſhorter than in the preceding ſpecies. According to Monſ. Gerard it is a variety of O. Natrix[k].—Native of the South of Europe.

28. This is a very ſtrong-ſmelling plant, with the odour of Theriaca, and not very clammy. Leaves oval, flattiſh, ſerrate only at the top, not fleſhy. Peduncle the length of the awn. Calyxes viſcid[l].

Root large and wrinkled. Stems more or leſs upright, commonly a foot high. Leaflets oblong, villoſe, toothed at the end. Flowers large, yellow, ſolitary, on a peduncle elbowed at two thirds of its length, whence ſprings a thread like an awn. The upper part of the flower is rayed with red lines. Legumes oblong and villoſe. The whole plant is viſcid and has a reſinous ſmell[m].

Monſ. Villars inſiſts that O. viſcida of Linneus is no more than a variety of this, only more upright, more viſcid and ſucculent, with longer leaves, and growing in woods.

Native of the South of France, Spain and Portugal, Carniola and Switzerland. Ray obſerved it firſt in Sicily, at Capo Paſſaro, then by the river Arve near Geneva, and about Montpellier abundantly: he remarks that the Sicilian plant is larger and higher than the others.—It was cultivated here in 1683, by Mr. James Sutherland[n].

29. Stem erect, panicled. Stipules awl-ſhaped, minute. Leaflets ſomewhat channelled, three-toothed at top, with ſome obſolete toothlets at the ſides. Raceme terminating, ſmall, hiſpid-glutinous. Flowers purple[o].]

Stalks ſhrubby, a foot and half high, dividing into ſlender branches very full of joints. Leaflets narrow, thick, fleſhy, on ſhort foot-ſtalks. Flowers at the ends of the branches in looſe panicles, ſome of the peduncles ſuſtaining two, and others but one flower; they are of a fine purple colour, and appear in June; the ſeeds ripens in ſeptember.

Native of Spain and Portugal. [Cultivated before 1759, by Mr. Miller.

30. Stem erect, panicled, pubeſcent-viſcid. Leaflets obovate, blunt, recurved, channelled, plaited, ſomewhat toothed, curled. Stipules bifid, embracing, toothed, hairy and viſcid, as is the whole plant. Flowers lateral, axillary, ſolitary, on a very ſhort peduncle. Calyx five-parted; ſegments ſhorter by half than the corolla, almoſt equal, three-toothed. Corolla yellow, the ſize of the leaves; with the ſtandard ſtreaked of a blood-red colour on the outſide, as in O. Natrix, which it reſembles very much; but differs in being curled, more viſcid, and having awnleſs peduncles, which, when the flowering is paſt, are very much recurved, inſomuch that the fruit approximates to the ſtem[p].

Native of Spain. Cultivated in 1752, by Mr. Miller[q]. It is omitted in the ſeventh and eighth editions of the Dictionary.

31. Plant ſtrict, viſcid, inodorous. Leaves thickiſh, leſs than thoſe of O. Natrix but thicker. Stipules ſpreading, recurved. Peduncles lateral, with an awn the length of the petiole. Flowers like thoſe of O. Natrix, yellow ſtreaked with red. Perhaps it may be a variety of O. criſpa.—Native of Spain[r].]

32. This is a very beautiful low ſhrub, riſing with ſlender ſtalks about two feet high, dividing into many branches. The flowers come out in panicles at the ends of the branches upon long peduncles, which for the moſt part ſuſtain three large purple flowers. Legumes turgid, about an inch long, hairy, incloſing three or four ſeeds.

[Stems many, woody, a foot high, ſmooth, round, ſtraight, with frequent joints, divided into ſhort branches. Stem-leaves ſeſſile; branch-leaves petioled. Leaflets ſmooth, unequally ſerrate, fleſhy, ſhining. Stipules ſtriated, dividing into unequal ſegments at top; according to Linneus four-awned and dry. Peduncles alternate, longer, contained within leafleſs ſheaths. Calyx five-parted, ſubvilloſe, with equal linear ſegments. Flowers nodding, forming handſome bunches, red or purple. Legumes hoary, longer[s].

Native of the South of France, on hills and mountains. Cultivated in 1748, by Mr. Miller. It flowers in may and june; and varies with white flowers[t].

33. Stem round, ſtriated, ſomewhat villoſe, a foot and half or two feet in height. Leaves petioled, ſerrate-toothed, with the teeth alternately larger and ſmaller, villoſe, large; the end leaflet larger and rounder than the others. Stipules green, ſheathing, obſoletely ſerrate, with longitudinal prominent nerves. The flowers form handſome bunches at the ends of the branches; they are on a long peduncle, frequently three together, each on its proper pedicel, of a purple colour. The ſtandard is very large, roundiſh[u], and pubeſcent. The wings ſhorter than the keel: the calyxes ſurrounded by three, cordate, approximating, ſhorter bractes.

It differs from the preceding in having a higher ſtalk, with wider leaflets. The ſtipules alſo in this are of the ſame colour with the leaves, and always leafy; whereas in the preceding they are ſhrivelled, and on the flowering ſtem leafleſs[x].

Mr. Miller deſcribes the corolla as pale yellow, which is certainly a miſtake, it being purple: in other reſpects his deſcription accords well enough with the plant.—It is a native of Switzerland, and was cultivated here in 1570, by Mr. Hugh Morgan, as appears from Lobel. It flowers from may to july[y].

34. This ſhrub is very much branched, ſomewhat ſpreading, and armed with ſtout thorns. Leaves petioled. Leaflets oblong, bluntiſh, even. Legumes petioled, linear, toruloſe, acute, even: containing five or ſix ſeeds.

Native of the Cape of Good Hope, where it was found by Thunberg[z].

35. Leaflets in fives, beſides the minute ſtipules[a].—Native of the Cape.

In the Species Plantarum Linneus deſcribes it under the name of Lotus, as a ſmall ſhrub, with filiform ſtiffiſh branches. Leaves petioled, with white hairs ſcattered over them on both ſides. Stipules the ſize of the leaves, lanceolate-ovate. Peduncles axillary,

[f] Ger. prov. [g] Hort. kew. [h] Linn. ſpec. [i] Linn. ſpec. and ſyſt. [k] Idem. [l] Linn ſpec. [m] Villars. [n] Hort. kew. [o] Linn. ſpec. [p] Linn. ſpec. [q] Hort. kew. from Mill. dict. ed. 6. long.

long. Legumes smooth, half as long again as the leaves.

36. This resembles O. minutissima, and has been taken by most authors for the same plant. Allione and Villars however regard it as distinct. The stems are of the same size, and have the same habit; but in this the whole plant, not excepting the fruit is villose and a little clammy; the leaflets are round, with the teeth straight and shallow; the stipules are russet, less hard and toothed, not blackish awned and entire; the calycine leaflets are less hard, shorter, and do not terminate in an awn; the flower is smaller, and yet is of the same length with the calyx, as well as the fruit.

It is singular, that in autumn, the petals become so small, as to be concealed under the germ, at the bottom of the calyx, so as not to be seen; the fruit however is not on this account abortive. All parts of the flower are straight, distinct, not touching each other, but pale and flat, and seeming to be the commencement of a regular flower of four unequal petals. This plant is more frequently found thus, than with the flowers developed, coloured, and equal in length to the calyx. Hence the name of fubocculta[1].

Native of Dauphiné, the county of Nice, &c. Allione affirms it to be perennial; but Villars rather takes it to be biennial.

37. This approaches to the preceding and the minutissima in size, but is a little different in habit. A hard, knobbed, perennial root, full of tubercles, furnishes several creeping stems, commonly simple, from four to six inches in length. They have few leaves on their lower part, and at top have a parcel of yellow flowers in a raceme. Stipules small, acute, toothed, semicordate. Leaflets almost triangular, truncated on the upper edge which is toothed, rayed or grooved on their upper surface, of a deep green colour. Peduncle a line and half in length. Calyx villose, almost as long as the corolla, with linear segments. Petals yellow. Legume villose, a little clammy, oval, inclosed within the calyx. The whole plant has the habit rather of Medicago falcata than an Ononis.

Native of Dauphiné, but rare[2]. Monf. Villars does not think that the fynonyms of Monf. Gouan belong to this plant.]

38. This is a perennial plant, from whose roots come out several pretty strong branches, which spread and incline towards the ground. Leaves narrow, very little hairy. The flowers come out in loose panicles at the end of the branches; they are yellow, and are succeeded by smooth turgid pods about half an inch long, each containing two or three kidney-shaped seeds. It flowers in july; and the seeds sometimes ripen here in the autumn. It was discovered by Dr. Houstoun, at La Vera Cruz in New Spain, whence he sent the seeds to England. This species is omitted in the quarto edition of the Dictionary.

PROPAGATION AND CULTURE.

2, 3. The common wild sorts of Ononis are very troublesome weeds in pastures and corn fields; the roots spreading and multiplying greatly in the ground, and being so tough and strong, that the plough-share will scarcely cut through them. They are only cultivated in botanic gardens.

1. 4, 5. Are hardy plants, like the others, cultivated only in botanic gardens.

7. A hardy annual plant, propagated by seeds, sown in the place where they are to remain, and requiring no other care but to thin them where they are too close, and to keep them clean from weeds.

8. This rises easily from seeds in the open air, and may be managed as the preceding, together with the other annual hardy sorts.

28. This is propagated by seeds, sown thin in drills upon a bed of light earth. When the plants come up, keep them clean from weeds till autumn; then take them up carefully, and transplant them into the borders of the pleasure garden, where they are to remain: the second year they will flower and produce ripe seeds, but the roots will continue several years, and are very hardy.

[The general practice is to consider this species as tender. Mr. Miller's treatment may suit it in mild winters; but it will be prudent to keep some plants in the green-house. In the course of two or three years it is apt to grow out of form, and therefore is generally renewed by seeds, which it produces in abundance; or kept closely cut in. It is also easily increased by cuttings[3].]

29, &c. The shrubby sorts are propagated by seeds sown upon a bed of light earth in april. The plants will come up in may, when they must be kept clean from weeds, and if they are too close, some of them should be carefully drawn up in moist weather, and transplanted at four or five inches distance: in the autumn they should be transplanted again to the places where they are to remain. Those plants which were left growing in the bed where they were sown, must be treated in the same way. These will not thrive in pots. They flower the second year, when they make a fine appearance, during the continuance of their flowers.

The twenty-ninth sort is too tender to thrive in the open air in England, unless it be planted in a warm situation, and in very severe frost covered to protect it. The seeds of this must be sown on a warm sheltered border, being impatient of cold.

The thirty-second will thrive very well in a shady border, and produce seeds in plenty.

[According to Mr. Curtis, the situation it affects is dry and sandy, but it is by no means nice as to soil or place, and is so hardy as to bear the severity even of a hard winter. In the collections about London it is frequently found in pots, and kept with greenhouse plants. The best mode of raising it is from seed.

The thirty-third sort flowers in our open borders, and ripens its seed, by which it is in general propagated. It may also be increased by slips, is very hardy, and easy of culture. Its beauty has gained it a general admission into our nurseries[4].]

DESCRIPTIONS, *&c.*

Thefe are in general tall large herbaceous plants, with great leaves like thofe of Acanthus, prickly and frequently tomentofe. Roots biennial. The fixth has the flower growing clofe to the ground; and the third is faid to be perennial.]

1. Cotton Thiftle the firft year puts out many large downy leaves, finuated on their edges and very prickly; they fpread on the ground, and continue the following winter. In the fpring the ftalk arifes in the middle of the leaves, upon dunghills or good ground growing five or fix feet high, and dividing at top into many branches, which have leafy borders running along them, indented, and each indenture terminated by a fpine. The ftalks are terminated by fcaly heads of purple flowers, appearing in june. To thefe fucceed oblong angular feeds crowned with a hairy down.

[The whole plant is generally covered with a clofe down, giving it a whitifh green colour. Root-leaves finall, waved and pinnatifid. Stem-leaves oval-lanceolate, decurrent, the lower ones very large, with deep triangular teeth; thefe again toothed, each tooth terminated with a fharp whitifh fpine, being the elongated nerves increafed in thicknefs and rendered rigid juft before they approach the margin. Upper leaves lanceolate, with a few diftant teeth terminated by fpines. The decurrent membranes are alfo irregularly toothed, each tooth furnifhed with fimilar fpines, which proceed from the ftem, and extend the membranes. Flowers fimple, upright, terminating. Calyx of numerous expanding awl-fhaped fcales, terminating in fharp fpines. Florets purple, fometimes white [a]. Seeds obovate, a little flattened, faintly angular, wrinkled, blackifh; crowned with a down, which is flightly hifpid when magnified. Receptacle reticulated with fquare membranous cells, like a honeycomb. It is diftinguifhed from the Thiftles by the laft circumftance; and when the flowering is over, the innermoft fcales of the calyx clofe ftrongly together. In the Thiftles, as foon as the feed is ripe, the firft hot day opens the heads, expands the pappus, and the leaft wind carries away the feeds: but in this plant they remain fhut up, and ftrongly defended; nor can they commit themfelves to the earth, or be eaten by birds, till long expofure to the weather has decayed the calyx; on this account, they afford fuftenance to birds late in the year. It is not very fubject to the depredations of infects, and it is defended by its ftrong fpines from the attacks of moft quadrupeds [b]; the afs alone will fometimes browze on it.

The receptacle of the flowers, and the tender ftalks peeled and boiled, may be eaten in the fame manner as Artichokes and Cardoons. The ancients thought this plant a fpecific in cancerous cafes [c]; fome of the moderns recommend its ufe externally in a cancer of the lips and face. According to Scopoli, a decoction of the root is reckoned a fpecific in a recent gonorrhœa.

Native of Europe, on dry banks and in wafte places near habitations, feldom in open fields. It flowers in june and july.

Its names in Engliſh are Cotton Thiftle, Oat Thiftle, wild White Thiftle, Argentine or Silver Thiftle; in Yorfhire Pig-leaves.]

2. This rifes with a taller ftalk than the former; the leaves are much longer and narrower, and the indentures on their fides are regular, ending in fharp fpines. The heads of flowers are larger, and the fpines of the calyx are longer than thofe of the firft fort.

[The ftem has fix prickly wings; the peduncles are naked. The feeds have tranfverfe wrinkles, and are crowned by a feffile egret of open feathered hairs, fhorter than the tube of the floret, and even than the calyx: the feeds are more lengthened out than thofe of the preceding, which have none of the tranfverfe wrinkles, and the hairs of the egret are lefs feathered [d].

According to Linnæus, it is a hoary afh-coloured plant; the ftem has waved wings ending for a fpace below the calyx, the lower fcales of which are lanceolate, bent back and hooked.

Receptacle flat, alveolate, and within each cell accompanied with a very fmall chaff, adhering to the bafe of the feed, and falling with it. Seeds obovate, compreffed-rhomb-fhaped, ftriated with a few longitudinal raifed lines, and tranfverfe obfolete wrinkles between them, afh-coloured. Pappus, egret or down twice as long as the feed, caducous, with filiform rays, very frequently toothletted, almoft equal, united at the bafe in a ring.

The feeds of the firft fpecies are in every refpect like this, except that they are fomewhat fmaller and rufefcent. The falling of the chaff with the feed is fingular in this genus [e].

Native of the South of Europe.] Mr. Miller fays, Spain, Portugal and the Levant. [Mr. Ray is furprifed that Botanifts fhould fetch this plant from Illyria, when it is common not only in Italy and Sicily, but in the South of France: he found it abundantly about Orange.—It was cultivated here in 1640, as appears from Parkinſon.

3. Native of Siberia. Introduced in 1784, by Mr. John Bell. It flowers in auguſt, and is perennial [f].]

4. This grows to the height of nine or ten feet; the ſtalks divide into many branches; the leaves are

[a] Woodw. Mſs. [b] Curtis. [c] Withering. [d] Villars. [e] Gærtner. [f] Hort. kew.

longer than in any of the other species; the heads of flowers are large and of a purple colour.

[Native of the South of Europe. Miller says, Spain and Portugal; Linnæus, Portugal and the South of France.—Cultivated in 1692, in the botanic garden at Oxford, as appears from Plukenet[a]. Ray muſt have had it much earlier, for in his hiſtory, publiſhed in 1686, he ſays: "Carduum hunc Cantabrigiæ olim "in hortulo noſtro ahimus, e ſemine Londino ac- "cepto ortum."

5. This is an annual plant, of a middle nature between the *arabicum* and *Acanthium*. Stem from a palm or foot to three feet in height, and very tomentoſe. Root-leaves lanceolate, a foot and half long or more, a palm in width, cloſely tomentoſe and hoary; ending in a pinnatifid petiole, ſinuate-pinnatifid and prickly. Stem-leaves running down the ſtem. Peduncles ſolitary, one-flowered, ſhort, ſcarcely an inch long, curled with one or two decurrent leaflets. Calyx more ovate, and more cobwebbed-tomentoſe than in the reſt, the ſize of a large walnut: ſcales more erect and more lanceolate than in *O. Acanthium*, leſs than in *O. arabicum*; hence the calyxes are leſs ſquarroſe, or more imbricate. Corollas purple, very narrow.

It differs therefore from *O. Acanthium* by its lanceolate tomentoſe-hoary leaves; which in that are ovate and greeniſh, ſcarcely tomentoſe except the young ones: by its imbricate calyxes, with lanceolate ſcales, the lower and outer ſhorter: whereas in *O. Acanthium* the calyxes are ſquarroſe, with awl-ſhaped ſcales, all nearly equal, namely the outer of the ſame length with the inner ones.—Native of the Levant[b].

6. Root biennial, fuſiform, half a foot long, ſtraight, black and irregular on the outſide. Stem ſingle, not more than two inches in height, erect, terminated by a ſeſſile flower. Leaves of the firſt year radical; of the ſecond cauline, many, cluſtered eſpecially at the top of the ſtalk and ſpreading out in a ring, ſo that the plant when ſeen from above appears to be ſtemleſs; they are petioled, tomentoſe and hoary on both ſides, oblong, pinnatifid, thickiſh, veined, ſomewhat wrinkled at the back, tooth-ſpiny at the edges, pungent and ſquarroſe. The petioles of ſome of the inner leaves bear a ſeſſile flower, and are then round and thick, whereas at other times they are flat at top; they may perhaps more properly be called pedunckes, or one-flowered branchlets, ſpringing from the ſtem, and furniſhed with a leaf next the flower. Calyx ſmooth, green, pungent and ſquarroſe, with the inner ſcales erect and purple. Florets quite white. Seeds angular. Down hairy, prickly-hiſpid when examined by a glaſs[c].

The native place of this ſpecies is not known. It was cultivated in 1739, by Mr. Miller, and flowers in July and auguſt[d].

Cavanilles has a plant, which he names O. uniflorum, a native of Catalonia, that ſeems to be the ſame with this. He deſcribes the root as brown, the ſpines of the leaves as yellow, the flowers as ſolitary and ſeſſile, the ſcales of the calyx as numerous and ſmooth, the outer ones ſhorter, all ending in a rigid thorny point. Receptacle naked, honeycombed. Seeds crowned with a long down. He makes no mention of any ſecondary heads of flowers, nor are any repreſented in the figure. He does not mention the colour of the florets.]

7. This riſes with an upright branching ſtalk ſeven or eight feet high; the leaves are long and regularly ſinuated on their borders, like pinnatifid leaves; the heads of flowers are very large, and the calyxes very ſquarroſe and prickly. It grows naturally about Aleppo.

PROPAGATION AND CULTURE.

Some of theſe plants were formerly cultivated for the table, but it was before the Engliſh gardens were well ſtocked with other eſculent plants; at preſent they are rarely eaten here. They require no culture, and if the ſeeds are permitted to fall, the plants will come up faſt enough.

DESCRIPTIONS, &c.

1. [Flowering top nodding, yelloviſh white. Corolla of Symphytum, ſcarcely five-cleft: but it has none of the rays which that has, ſo that the throat is naked. Corolla conſtantly white. The wild plant is never more than a foot high, and ſoft to the touch. Seeds, which Gærtner calls nuts, ſmall, ſtony, ovate, with a little beak, ſlightly convex on one ſide, angular on the other, with a triangular little area at the baſe, not perforated; the reſt highly poliſhed and ſhining, whitiſh aſh-colour, variegated with teſtaceous dots and very ſlender lines, one-celled, valveleſs. Seed ovate-acuminate, compreſſed a little, brown-bay, flattened by a capillary chord at the apex.

Native of Siberia: abundant on the calcareous rocks by the Wolga, but not deſcending to the Ukraine, where the laſt ſpecies is very common[a].

2. Native of the Levant. Pallas thinks that he has given a figure of this ſpecies, which he found growing near the Caſpian ſea, in the ſecond volume of his travels, *tab. L.* It is marked as a ſhrub by Linnæus.] Miller ſays that this and the preceding are generally biennial plants, at leaſt here; though ſometimes, when they grow out of the joints of walls, or the fiſſures of rocks, they will abide three or four years.

[a] Linn. [b] Gærtner.

3. [Root-

3. [Root fusiform, with a bark peeling off in scales, which are red as vermillion. Leaves long and narrow, rough, villose and whitish. Flowers terminating, resembling those of Symphytum[1]. Seeds or nuts larger by half than those of the first sort, bay ash-coloured all over, frequently marked on the side of the back with two whitish eyes surrounded with a brown ring; they are very smooth and shining, and sharply keeled[2].

Native of the South of Europe: Italy, France, Switzerland, Austria, Hungary. Cultivated here in 1683, by Mr. James Sutherland. It flowers from march to june[3].

β. The larger variety was observed by John Bauhin between Vienne and Lyons, and on the Euganean hills by Padua; by Ray near Lyons, on the road to Geneva[4]. The roots of both yielding a very fine red dye, might serve all the purposes of Anchusa tinctoria or Alkanet[5].

Dr. Smith thinks that Columna's plant is a different species from this, being less hairy, and the bristles on the leaves curiously stellated at their base[6].]

PROPAGATION AND CULTURE.

These plants being natives of rocks, are best cultivated on a wall or rubbish. Sow the seeds soon after they are ripe, laying the stalks over the place, to shade them from the sun. When the plants are well established, if they are permitted to scatter their seeds, they will maintain themselves very well. In the common ground they are short-lived and apt to rot.

[OOSTREDYKIA. See *Crusnia*.

OPERCULARIA. (*From* operculum, *a lid.*)
Lin. gen. Schreb. n. 152. & *p.* 819. *Gærtn. t.* 24.
Rubioides. *Soland.* An Pomax. *Soland.*
Class. 4. 1. Tetrandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth common* one-leafed, bell-shaped, three to six-flowered, six to nine-toothed: teeth acute, unequal: permanent.
Perianth proper none.
COR. *Universal* equal.
Proper one-petalled, funnel-form: *mouth* four or five-cleft, erect.
STAM. *Filaments* four, inserted into the receptacle. *Anthers* distinct.
PIST. *Germ* inferior, immersed in the receptacle. *Style* filiform. *Stigma* thickish, bifid.
PER. none.
SEEDS solitary, convex on one side, grooved on the other.
REC. *Common*, flat above, closing the aperture of the calyx below the teeth, below pyramidal, grooved-angular: the angles continued into partitions, by which the cavity of the calyx is divided into cells equal to the number of seeds: deciduous.

ESSENTIAL CHARACTER.

Flower compound. *Cal. common* one-leafed, unequally toothed, closed by a common receptacle, flowering above, seeding below, falling when ripe.

SPECIES.

1. Opercularia umbellata.

Rubioides aspera. *Soland. Mss.*
Corollets four or six, border four or five-parted.
3. Opercularia diphylla.
Gærtn. fruct. 1. 113.
Rubioides diphylla. *Soland. Mss.*
Common calyxes hispid.

DESCRIPTIONS, *&c.*

1. Florets in the disk three, separate. Corollets three-toothed. Stamen one. Style one, or sometimes but seldom two. Pericarp none, unless the common calyx of the flower be reckoned as such; it is bell-shaped, cut with seven or nine unequal teeth; the seeds are inclosed within the cavity of it, equal in number to the corollets. Common receptacle fungous, above flat, corolliferous, rounded, exactly closing the aperture of the calyx near the teeth. Proper receptacle a small scar at the inner angle of the cells, from which the seeds hang downward. Seeds in each partial cell one, in the whole fruit commonly three, seldom four, obovate, variously shagreened with tubercles and wrinkles, slightly convex on one side, angular with a prominent groove on the other, black.—Native of New Holland.

2. Corollets to each calyx four or six, funnel-form, white: tube widening at top, twice as long as the calyx; border four or five-parted, segments lanceolate, acute, shorter than the tube. Stamens four or five, inserted into the receptacle not the corolla. Anthers separate. Style deeply bifid. Common calyxes heaped into a globular pedunculed head, almost hemispherical, grooved, with from six to nine unequal acuminate teeth. Common receptacle almost hemispherical, four or six-grooved. Seeds four or six, obovate, brown, convex on one side, and having two raised fungous white grooves on the other.—Native of New Zealand.

3. Heads as in the preceding, but little more than half the size. Common calyxes hispid with rigid bristles. Cells three or four, below as many four-flattened flowers. Seeds small, elliptic, white, roughened on every side with irregular tubercles, slightly convex on one side, angular on the other with a raised wrinkled longitudinal groove.—Native of New Zealand[7].

OPHIOGLOSSUM (*of Pliny. From* οφις, *a serpent, and* γλωσσα, *a tongue.*)

Lin. syst. 926. *Thunb. jap.* 328.
Stem flexuose angular, fronds superdecompound, pinnules alternate gashed.

DESCRIPTIONS, *&c.*

These are Ferns in habit and fructification, but not having the seed on the back of the frond, Ray did not include them among his hypophyllospermæ or true Ferns, nor has Dr. Smith treated of them among his Dorsiferæ.

According to Jussieu, the genuine Ophioglossums have a radical leaf, not convoluted, generally simple and nerveless, putting forth a spike usually simple and pedunculed. The spurious sorts have branched fronds, several times pinnate, or superdecompound, when young convoluted like the true Ferns, when older radiately spike-bearing in the circumference of the leaflets, the spikes sessile imbricately and distichally scaled: the genus therefore ought to be divided, as it is it constitutes a middle link between the Mosses and Ferns. Jussieu doubts whether the spike be male only, or as Hedwig is inclined to think, has both sexes in each cell of it.

1. Common Adder's-tongue has a fibrous root, and a single stem, round, very smooth, upright, simple or unbranched, from a hand or finger's length to a span or more in height; terminated by a distich, jointed, tongue-shaped, greenish spike, brown when ripe; subtended by a single, long-ovate, succulent, nerveless leaf, embracing the stalk with its base: the joints burst transversely when ripe, and throw out numerous very minute seeds[a]. The leaf is commonly quite entire, but it is sometimes sinuated, angular, or slightly lobed with small appendages on one or both sides. Bauhin has also described a variety which is smaller with a roundish leaf. The spike is naturally simple, but sometimes the stalk divides at top, each branch supporting a spike, and the spike itself sometimes divides into two or three[b].

[a] Lightfoot. [b] Bolton and Withering.

Many of the stalks are barren, producing a leaf only, without a spike.

The common people make an ointment with the fresh leaves, and use it to green wounds, calling it Adder-spear ointment. It is a very ancient application, recommended by Matthiolus, Tragus and others[a].

Native of Europe, in moist meadows. In England it is not uncommon; in Scotland, but not very common; in Ireland, in meadows by the banks of rivers, that leave sand and mud after floods. With us it was found by Mr. Newton by Bow, Hackney Marsh; by Dr. Sibthorp at Bosley, Cowley, Headington and South Leigh in Oxfordshire. In Granchester meadow, Whitwell, &c. in Cambridgeshire. At Bedingham near Bungay, and near Mettingham-castle in Suffolk. Broadmoore near Birmingham; and near Blymhill in Staffordshire. Love-lane near Derby. Observed in meadows and by the sides of rivulets in the north of Yorkshire by Mr. Curtis. Between Otpringe and Ore in Kent. Near Hampstead and Harefield in Middlesex. Eastwood and Gedling in Nottinghamshire.

2. This is a very small plant, not an inch high. Root bundled, filiform. Leaves few, radical, petioled, quite entire. Scape filiform. Spike the length of the scape, a little thicker.—Native of the Cape of Good Hope. Found there by Thunberg[a].

3. Herb annual, stemless, two inches high, erect. Leaf single, petioled, acute, quite entire, smooth, the length three times as great as the breadth. Spike solitary, fastened to the base of the leaf, simple, linear, compressed, straight, equal, divided on both sides by many lateral notches, emitting a yellow pollen, or rather perhaps very minute seeds[a].—Native of Portugal, China and Cochinchina.

4. This plant rises commonly to the height of five or six inches above the root[a].—Native of Jamaica and the continent of South America.

5. Native of South America.

6. Native of the East Indies, parasitical on trees, from which it hangs down[a].

7. This is a climber, and rises to a considerable height on trees: the stalk is smooth and slender, the leaves of a nervous texture, and sometimes divided into two or more unequal parts[a]. Pinnas cordate-hastate or hastate-lanceolate. Fronds not opposite, but conjugate at the tubercles of the branches.

Stem fustiruncose, long, slender, round, branched. Fronds unequally pinnate, with about four pairs of leaflets; which are hastate-lanceolate, the lobes rounded at the base. Spikes linear, distich, longish, fastened to the leaflets[a].

Native of both Indies, China and Cochinchina, and every where within the tropics.

8. Very nearly allied to the preceding. Fronds remote on the stem, three or four-lobed.—Native of the East Indies[a].

9. Stem filiform, two-angled, smooth, scandent. Fronds alternate; lower three-parted, the middle lobe lanceolate, gash-serrate; lateral ones bifid, serrate, smaller; the upper bipinnate with gashed pinnules; the uppermost flowering, with linear, equal, entire pinnules.

It differs from O. flexuosum in its superdecompound frond, alternate not opposite pinnæ, alternate pinnules, gash-pinnatifid, with serrate incisures, and the flowering pinnules linear. It differs from O. scandens in having the outmost pinna not elongated, not eared at the base, and the frond decompound with about three pinnæ, three-gashed.—Native of Japan[a].

Ophioglossum zeilanicum. *Heart.* the same with Acrostichum quercifolium of Retzius, and Osmunda trifida. *Jacq. collect.* 1.

[b] Browne. [a] Linn. [a] Browne. [a] Loureiro.
[a] Linn. suppl. [a] Thunberg.

Class. 5. 1. Pentandria Monogynia.
Nat. order of *Stellatæ*. *Gentianæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, erect, compreſſed, five-toothed, equal, permanent.
COR. one-petalled, funnel-form: *tube* inflated at the baſe: *throat* almoſt cloſed with hairs: *border* five-cleft, blunt, ſpreading.
STAM. *Filaments* five, filiform, very ſhort, inſerted into the tube. *Anthers* oblong, the height of the tube.
PIST. *Germ* biſid, ſuperior. *Style* filiform, the length of the ſtamens, thicker above. *Stigmas* two, blunt.
PER. *Capſule* two-lobed, wide, bluntiſh: lobes oblong, divaricated, two-celled: opening inwards with a contrary partition.
SEEDS numerous, angular, fixed all round to an oblong pedicelled receptacle, looſe in the middle of each cell.

ESSENTIAL CHARACTER.

Cor. funnel-form. *Germ* biſid. *Stigmas* two. *Fruit* two-lobed.

SPECIES.

1. Ophiorhiza Mungos.

Leaves lanceolate-ovate.
2. Ophiorhiza Mitreola.
Lin. ſpec. 213. *ſyſt.* 197. *Reich.* 1. 426. *Swartz obſ.* 59. *t.* 3. *f.* 2.
Mitreola. *Lin. hort. cliff.* 492. *Gron. virg.* 28.
Mitra. *Houſt.*
Leaves ovate.
3. Ophiorhiza ſubumbellata.
Forſt. flor. auſtral. n. 66.
Stem ſhrubby, leaves lanceolate acute, umbels axillary trifid.

DESCRIPTIONS, *&c.*

1. Stem ſimple. Leaves oppoſite, quite entire, ſmooth, with obliquely tranſverſe nerves, petioled. Peduncle terminating the ſtem with a corymb of ſimple or biſid ſpikes, digeſted umbel-wiſe, from one centre, and ſpreading. Flowers ſeſſile from the upper ſide of the horizontal ſpike[a]. Capſule tranſverſely wider or two-lobed: lobes oblong, diverging, blunt, above compreſſed to a membranaceous edge, below ſubventricoſe, with a groove along the middle on each ſide, two-celled, opening along the upper edge: partition very narrow, contrary to the valves. Receptacle long, ſlender, cylindric-acuminate, attenuated below into a very ſhort pedunele, and faſtened on both ſides to the middle of the partition, in other parts looſe, aſcending from the horizontal line, deciduous in maturity. Seeds very numerous and ſlender, variouſly angular, remarkably acuminate towards the navel, ferruginous[b].

Native of the Eaſt Indies. Called in Ceylon *Ekanteeya* and *Naphawalli*, from Nagha the Ribband Snake, for the bite of which the leaves of this plant are accounted a ſpecific[c]. This is quite different from the true *Radix Mungos, Kæmpf. amœn.* 573. as appears, from a compariſon of the fruits[d].

2. Roots from the lower joints of the ſtem in bundles, long, filiform, white. Stem herbaceous, a foot high, ſimple or branched, erect, four-cornered at bottom, towards the upper part roundiſh, ſmooth, looſe. Leaves petioled, oppoſite, lanceolate-ovate, acuminate, entire, ſmooth on both ſides. Leaflets in the axils of the larger ones. Peduncles terminating, dichotomous, looſe; flowers minute, ſeſſile, directed one way, diſtinct, white: and a ſolitary flower in the forks of the peduncles. Calyx minute, five-parted, with erect ſegments. Corolla tubular, longer than the calyx; ſegments of the border ovate, acute, erect, often bent in: throat villoſe, white. Filaments from the middle of the tube. Anthers converging under the pile of hairs above the ſtigmas. Germ two-parted at the baſe, oblong. Styles two. Stigmas roundiſh, white, pubeſcent. Capſule at the baſe biſid, one-celled, two-valved; the valves opening at the ſide within longitudinally. Seeds numerous, inſerted into two receptacles faſtened to each valve. Annual; flowering in ſpring[e].—Native of America: in Virginia, and in Jamaica, in wet meadows on the banks of rivers.

3. Native of the iſland of Otaheite or Taheiti[f].

OPHIOXYLON. See *Buddlea*.

OPHIOXYLUM. (*From οφις and ξυλον. Serpentine wood.*)

Clematis indica, perſicæ foliis, fructu periclymeni. *Bauh. pin.* 304.

DESCRIPTION, *&c.*

Stem upright, round, quite ſimple. Leaves in fours placed croſs-wiſe, lanceolate-ovate, ſmooth, acuminate, petioled. Nectary like that of Narciſſus. Calyx biſid. Stamens two in the mouth of the corolla[g].

According to Burmann the ſtem is three-cornered, jointed, ſtriated, at each joint are three leaves, which are oblong acuminate, entire not ſerrate, in which they differ from thoſe of the Peaca-tree, whoſe form they reſemble: petioles ſhort. At the top of the ſtem are many ſhorts in a ſort of umbel. Stamens two.

This ſhrub, as Juſſieu deſcribes it, has three or four leaves in whorls: flowers glomerate, terminating, males mixed with the hermaphrodites, two-ſtamened only, with a cylindric entire crown at the throat of the tube, without any germ.

Berry ſeſſile, two-lobed, within a very ſmall three or five-cleft calyx, lenticular-compreſſed, two-celled, of a brick-red: pulp thin, firm: ſtones ovate, acuminate at both ends, but moſt towards the baſe, obſoletely wrinkled, thick, lenticular-compreſſed, one-celled. Seeds ſolitary, ovate, narrowed upwards, compreſſed a little, pale.—The freſh fruits, according to Rumphius, have a twin and very blunt berry, compoſed of two globes, as in the Honeyſuckle, and filled with a watery pulp. Gærtner has deſcribed them as they appeared to him, and as Burmann has repreſented them. Rumphius's figure is not of this ſpecies, but of another, which Gærtner names *alba*, with

[a] Linn. zeyl. [b] Gærtner. [c] Linn. zeyl. [d] Gærtner. [e] Swartz. [f] Forſter. [g] Linn. zeyl.

oppofite cruciate leaves, white flowers, and black berries*.

They are both natives of the Eaft Indies.—Scarlet-flowered Ophioxylum was cultivated in 1690, in the Royal Garden at Hampton Court. It flowers in may and june*.

OPHIRA.

Lin. gen. Reich. n. 525. *Schreb. n.* 662. *Juff.* 321. *a Fe. Burmanno.*

Claff. 8. 1. Octandria Monogynia.

Nat. order of *Onagræ*, Juff.

GENERIC CHARACTER.

CAL. *Involucre* two-valved, three-flowered: *valves* lateral, kidney-form, emarginate, conduplicate, permanent.

COR. four-petalled, fuperior. *Petals* oblong, converging.

STAM. *Filaments* eight, the length of the corolla. *Anthers* ovate.

PIST. *Germ* inferior, turbinate, hifpid. *Style* filiform, fhorter than the ftamens. *Stigma* emarginate.

PER. *Berry* one-celled.

SEEDS two.

OBS. *It bears much refemblance to* Grubbia *of Berg-ius, which has a fuperior germ and fimple ftigma.* Mantiff.

ESSENTIAL CHARACTER.

Involucre two-valved, three-flowered. *Cor.* four-petalled, fuperior. *Berry* one-celled.

SPECIES.

1. Ophira ftricta.

Lin. fyft. 371. *Reich. 2. 189. mant.* 229.

DESCRIPTION, *&c.*

This is an upright fhrub, with oppofite, ovate-linear leaves, and lateral feffile flowers. Found in Africa by Burmann †.

Juffieu remarks that it is allied to Cornus, and that hence Grubbia is allied to Empetrum.]

OPHRYS (*of Pliny. From* οφις, *the eye-brow; one fpecies having been ufed either to blacken the eye-brows or to make them grow.*)

Lin. gen. n. 1011. *Reich. n.* 1096. *Schreb. n.* 1369. *Tournef. t.* 250. *Juff.* 65.

Claff. 20. 1. Gynandria Diandria.

Nat. order of *Orchidex.*

GENERIC CHARACTER.

CAL. *Spathes* wandering. *Spadix* fimple. *Perianth* none.

COR. *Petals* five oblong, converging upwards, equal: two of the fe exterior.

Nectary longer than the petals, hanging down, poſteriorly one fomewhat keeled.

STAM. *Filaments* two, very fhort; placed on the piſtil. *Anthers* erect, covered with the inner margin of the nectary.

PIST. *Germ* oblong, contorted, inferior. *Style* faſtened to the inner margin of the nectary. *Stigma* abſidete.

PER. *Capſule* fubovate, three-cornered, blunt, ſtriated, three-valved, one-celled, opening at the keeled angles.

SEEDS numerous, like faw-duſt. *Receptacle* linear, faſtened to each valve of the pericarp.

OBS. *O. Corallorhiza has four ſtamens or two in each cell.*

ESSENTIAL CHARACTER.

Nectary fomewhat keeled underneath.

Bulb ovate, scape round scorbed, leaf round fistular reflex, perforated in the middle to let the scape past.

DESCRIPTIONS, *&c.*

These plants are of the same natural genus with the Orchis, and all the elder botanical writers confounded them. Linnæus distinguished this natural order into genera from the nectarium, as he calls it; which in Orchis forms a horn or spur at the back of the flower, whereas the lip of it in this is a petal hanging down with a ridge or keel running along the back.

Some modern writers have very unadvisedly cancelled the whole class Gynandria, and removed this natural order into the class Diandria.]

1. The root is composed of many strong fibres, from which arise two oval veined leaves, three inches long, and two broad, joined at their base; between these springs up a naked stalk about eight inches high, terminated by a loose spike of herbaceous flowers, resembling gnats, composed of five petals, with a long bifid lip to the nectarium, a creft or standard above, and two wings on the side. Capsule angular, opening in six parts, and filled with small seeds like dust.

[Root affixed laterally to the stem, consisting of a thick bundle of fleshy fibres, more numerous and intricate than those of O. ovata. Stem from twelve to fifteen inches high, thickest at the base, firm and remaining long after the seeds are shed; without leaves, but cloathed with numerous embracing dry scales. Spike four or five inches long, cylindrical; flowers at the base rather scattered, upwards crowded. Bractes shorter than the germ, acutely lanceolate. Petals closely converging, oval; lip of the nectarium long, at first linear, but divided at the base into blunt divaricated lobes. Stamens inserted in two cavities in the upper lip of the nectarium; anthers yellow. Capsule on a triangular fruit-stalk, having a prominent rib at each angle, and one on each side, with intermediate furrows. The whole plant is brown, and closely connected in habit with Orobanche, Lathræa and Monotropa [x].

Native of several parts of Europe, as Sweden, Denmark, Britain, Germany, France, Austria, Switzerland, Italy, in woods and shady places. With us about Charlton, Gravesend, Maidstone, and Rochill in Kent; Selborne in Hampshire by Mr. White; Madingley-wood in Cambridgeshire; Aldborough in Suffolk by Ray; Heydon in Norfolk. Near Ingleton, and in Ossley park. Buckham wood in Cumberland. Near Kendal in Westmoreland. Not uncommon about Newton Cartmel; found there by Mr. Hall, who observes, that the woods in the part of Lancashire where he lives, are cut down every fifteen years; that for six or eight years after they are cut, this plant is not to be found, but as soon as the grasses are chiefly destroyed by the shade, it again makes its appearance, and in some places is pretty plentiful [y]. Mr. Blackstone observed it in White-Heath-wood by Harefield. It is also found in some woods in Scotland, but not common. It flowers in may and june. The names of Nidus avis, Bird's-nest, and Nid d'oiseau, are derived from the matting and twisting of the fibrous roots.

2. The root consists of thick white succulent obtuse fibres, branched like coral. Stem six or eight inches high, without any other leaves except sheathing stipulæ. Flowers in a thin spike, eight or ten in number, verging a little to one side of the stalk, and subtended each by an oval-lanceolate greenish bracte. Upper petals green, oval-lanceolate, converging in form of

[x] Woodw. Mss. [y] Withering.

pellucid puckered skin, giving them a silvery hue. Upper part of the stem naked, yellowish green, nearly round, smooth. Bractes linear-lanceolate, much longer than the germ, pale yellowish green. Flowers in a long thinly scattered spike; sometimes fifteen in number, but seldom more than four or five: the three outer petals linear, with reflexed margins, the upper one forming right angles with the others; the two inner thread-shaped, spreading, resembling the antennæ of an insect, deep reddish brown, fringed with short hairs, fixed to the upper lip of the nectarium, which is hooded, covering the stamens; lower lip three-lobed, side lobes linear, entire, middle somewhat ovate, bifid with reflexed margins, covered with a velvety down reddish brown, and with a blueish spot on the centre, which is naked. The whole extremely resembles a fly, to which this blue spot, as Dr. Withering observes, contributes much. The stamens are very short and loose, the anthers yellow[3].

According to Haller, the stem is eighteen inches high; the leaves scarcely an inch in breadth; the spike remarkably thin of flowers, seldom more than eight; the stipule (or bractæ) ovate-lanceolate, equal to the germ or longer; the germ sessile, long and slender; the staminous column without any beak; the anthers are evolved or come out of their case very readily.

Mr. Relhan remarks the slenderness of the stem, which is a character that strikes at first sight, adding that it is round, and smooth or even; bractes longer than the germs; flowers from four to eight, distant, which is another obvious character; lip of the nectary wide, hanging down, longer than the germ, dark purple, reflex at the sides, the segments rounded; the three outer petals spreading, green, the two inner filiform, dark purple.

Linnæus has not considered this as specifically distinct from the Bee Ophrys: but it is now generally agreed that they are different, as Haller, Jacquin, and our English botanists have decided them to be. Jacquin has given a full and exact description of the Fly Ophrys in his Miscellanea.

Native of Sweden, Norway, Switzerland, Austria, Carniola, France, Italy. I found it in flower at Vevay, on the banks of the lake of Geneva, may 24th 1779. In England it is not uncommon; as in Boston church-yard, and about Wrotham and Northfleet in Kent; Hatcfield in Middlesex; Croydon in Surrey; Hinton, Teversham, Fulbourn, Linton, the Devil's-ditch and Chippenham in Cambridgeshire; Bath-hills near Bungay, and Eartham-wood in Suffolk; Ray observed it in Essex, as well as the last two counties; St. Vincent's rocks near Bristol; Plumpton-woods near Ulverston; Rushton in Northamptonshire; Aslpy in Nottinghamshire: Barrowfield-wood, and Brigstear-moss in Westmoreland; generally in calcareous pastures. It flowers in may and june.

Some varieties of the Fly Ophrys are mentioned as growing in foreign countries: and Mr. Ray has a larger sort found by Mr. Dale in a pasture near Pestingford in Suffolk, and by Dr. Eales near Welwyn in Hertfordshire, at Greenhithe and by North Gray, by James Sherard, M. D. From the figure of John Bauhin, to which Ray refers, it will probably prove, says Dr. Withering, to be a different species.

13. Bee Ophrys has the stem about a foot high, leafy, round except between the fructifications, where it is compressed. Leaves alternate, lanceolate, sheathing, pubescent, nerved. Bractes longer than the germs, lanceolate. The three outer petals large, spreading, purple, with the keel and two nerves green; the two inner petals very small, hairy, reflex, green; lower lip of the nectary large, wide, but shorter than the petals, dusky purple mixed with yellow, three-lobed, the side lobes smaller, hairy, reflex, triangular, acuminate; the middle one very large, pubescent, three-lobed, bent down, the middle segment longer, acuminate; upper lip narrowed above with a point, longer than the lower lip, of a green colour. Filaments long: anthers very large. Germ longer than the petals, but shorter than the bractæ, large, deeply grooved.

[3] Woods. Mf.

The above description, which I made with great care from a living plant, is asserted by Haller to belong to the Ophrys muscifiora, and to contain nothing common to O. fuciflora. Let the skilful compare and judge.

According to Mr. Woodward, the stem is shorter than the foregoing, the leaves broader and shorter; the spike of fewer flowers; the bractes broader and shorter, but still longer than the germ; the three outer petals lanceolate, patent and even reflected, as long as the germ, purple with the keel and two nerves green, the tips green and folded; the two inner petals patent, linear, purplish on the inside, green without; upper lip of the nectarium lengthened into a deep-green proboscis, under which are the filaments and yellow anthers; lower lip of the nectarium large and broad, hairy, mottled brownish purple and yellow, divided into three lobes, the two upper near the top, short lanceolate, at first bent upwards, afterwards reflected, the middle one very large, three-lobed, the side ones short, angular, the middle one long, tapering to a point which is greenish yellow, and reflected.

Dr. Stokes describes the lower lip of the nectary as rusty brown, very much resembling a small humble-bee, inversely ovate, the side-lobes bent down, woolly, the edges bent in, the upper angles loose and upright, resembling the wings of the bee. Stamens yellow, inserted into the upper edge of the stigma, bursting, when the flower is expanded, from the membranaceous cases of the upper lip, and bending down on the surface of the stigma, continuing fixed to its edge. Anthers club-shaped, compound, resembling those of Orchis. Germ not wreathed (scrobed). It agrees much more nearly to Orchis in its structure, and confirms the propriety of Haller's generic characters.

According to Mr. Curtis, the stalk is from half a foot to a foot high; the leaves ovate-lanceolate, underneath silvery, with linear fibres, frequently imperfect and of a brown colour; bractes large, sheathing, green, and of equal length with the flowers, which are from three to six. Style long, upright, at the tip bending downwards, and again upwards. Filaments arising from the bottom of the style out of a nectariferous scale, hanging down, frequently adhering to the stigma, furnished at bottom with a small transparent gland or globule. Stigma covered with a viscid substance like honey, to which some small particles of the anthers frequently adhere. Capsule about an inch in length, brown. Seeds oblong, at each end membranous, transparent, reticulated, placed lengthwise to the inside of the keel of each valve.

Native of every part of Europe. In England this singularly beautiful plant is not uncommon on a calcareous soil near woods, and in meadows. Near London it is become so rare, as scarcely to be found with any certainty, owing to the rapacity of florists and dealers, who as Mr. Curtis observes very justly, root up all they find, without leaving a single specimen to chear the heart of the student in his botanic excursions. Mr. Aichorne has frequently gathered it near Charlton-church, and Chiffelhurst in Kent. It grows also on Trundle-down in the same county. Mr. Blackstone found it about Hatcfield. In Cambridgeshire it is abundant about Madingley-wood, Hinton, Teversham, Fulbourn, Burrough-green, Chippenham and Linton. In Bedfordshire at Bolnhurst. In Buckinghamshire at Brandenham. In Northamptonshire at Blatherwick and Asply. In Oxfordshire at Pently Hangings. About Eartham in Suffolk and Mulharton. On St. Vincent's rocks near Bristol. Carisbrook Castle in the isle of Wight. Great Comberton towards Woller's-hill, and Ledestone near Whitbourne in Worcestershire.

It flowers in june and july, and the seed is ripe at the end of august. The root appears to possess the same virtues with those of the Orchis whence Salep is made, but being much smaller is not worth cultivating on that account[4].

14. Stem six inches high, more or less according to its place of growth, round, smooth, covered below with leaves embracing it. Leaves next the root an

[4] Bibliotheca Botanica, p. 307. [5] Curtis.

inch

inch and half long, almoſt an inch broad, ovate-lanceolate, ſomewhat blunt, marked with impreſſed lines, ſmooth, ſpreading on the ground; thoſe of the ſtalk few, narrower and more pointed. Flowers from three to ſix, in a thin ſpike. Petals pale green, the three outer largeſt and the length of the lip, of theſe the two oppoſite ovate-lanceolate, obtuſe, bent ſomewhat inwardly, the uppermoſt narrowed, with the edges rolled back, the two innermoſt ſhorter, lanceolate, upright or bent a little back, generally ſomewhat truncated at the tip: the lip nearly orbicular, below concave, above convex, the ſides bent down, at firſt of a bright purple brown colour, ſoon changing to a yelloviſh hue, marked in the middle with a ſpot conſiderably reſembling the Hebrew letter ת, differing however in its form in different flowers, covered thickly with ſhort hairs, eſpecially at the ſides, where it for the moſt part projects, the ſpots excepted, which are ſmooth and gloſſy. Filaments whitiſh. Anthers club-ſhaped, yelloviſh; the cafes in which they are contained open through their whole length, their edges membranaceous, and near the top, ſo tranſparent, that the colour of the anthers is ſeen through them. Stigma concave, purpliſh, marked on each ſide with a greeniſh gland[1].

Mr. Woodward diſtinguiſhes it from O. apifera with which Linneus and foreign botaniſts in general have confounded it. The ſtem is not near ſo high, the leaves are ſhorter, but otherwiſe ſimilar, the bractes narrower, the flowers ſmaller, the three outer petals bluntly ovate-lanceolate, greeniſh, ſhorter than the lip; which is ſomewhat heart-ſhaped, but not lobed.

It is ſurpriſing that Linneus, who allows that theſe three plants are conſtant in their differences, ſhould not diſtinguiſh them, when the lip of the nectarium in one is four-lobed, in another five-lobed, and in the third only ſlightly emarginate; not to mention the comparative length of the petals and lip in the two laſt, which are moſt alike; a ſpecific character ſtrictly juſt and admiſſible.

It is a ſtrange aſſertion of Haller, that in an advanced ſtate the projection of the lip being bent back, and the lip then appearing heart-ſhaped, Ophrys apifera becomes the ſame with O. aranifera. It is ſufficient on this to obſerve, that O. aranifera is the earlieſt of the three, appearing in may; whereas the Fly appears in june, and the Bee uſually in july[2].—Our aranifera however is not the *arachnites* of foreign authors, or Orchis araneam referens of Caſp. Bauhin, which is not a native of Britain, but of Switzerland, Italy and other parts of the continent. Dr. Smith found it abundant in all the graſs-plats of the Villa Borgheſe near Rome, with a ſtem twelve or fourteen inches high; the lip of the nectary is more expanded, membranous and undulated in the margin. It is well figured in Beſler's Hortus Eyſtettenſis, and an accurate figure and deſcription of it is given by Haller. It flowered in Mr. Curtis's garden at Brompton, june 18. 1794.

Our plant is commonly known in this country by the name of Bee Orchis with green wings, the petals being altogether of an herbaceous colour, whereas in the *apifera* three of them are pale purple; but they differ not only in colour, but very materially in ſhape, as obſerved above: this flowers alſo in mild ſeaſons as early as march. The nectary, which at firſt is of a bright and very rich brown colour, ſoon changes to a faded yellow green: when the flowering is over, the petals incline forward, and cloſe over the nectary[3].

The flower is not ſo beautiful as that of the two preceding ſpecies: it is fancied by ſome to reſemble a bee, by others a ſpider; from the breadth of the lip, and its being marked with different ſhades of brown it derives its reſemblance to the latter[4]. Others have diſcovered a likeneſs to a ſmall bird in the flower[5].

Native of England, in chalky paſtures, as about Northfleet, Bocton church-yard and other places in Kent; Leatherhead in Surrey; near Wheatley, between Witney and Burford, Caverſham Warren, and Stansfield in Oxfordſhire; about Bratham near Tadcaſter; about Bury in Suffolk; found by Sir Thomas Gery Cullum; ſeveral places in Cambridgeſhire; as Shelford, Abington, Hilderſham, Bartlow. At Hilderſham I have frequently found it in very great abundance, but the exterminators are very diligent wherever they can find it.

15. Bulb ſingle, round or ſomewhat oblong, with a few thick fibres from the crown. Stem about ſix inches high, round and ſmooth. Root-leaves two or three, ſheathing the ſtem, lanceolate, acute, ſmooth, of a ſhining yelloviſh green, marked with parallel veins; on the ſtem one or two ſeſſile awl-ſhaped leaves. Spike an inch or an inch and half long, of numerous flowers. Bractes lanceolate, acuminate, at the lower part of the ſpike equal to or ſomewhat longer, on the upper part ſomewhat ſhorter than the germ; which is oval, ſeſſile, the upper part tapering to a ſort of fruit-ſtalk, whence hangs the flower obliquely nodding; the three outer petals ovate-lanceolate, ſomewhat converging; the two inner broad at the baſe, with a linear-lanceolate termination: lip of the nectarium deeply trifid, cruciform; ſegments lanceolate. The flowers are greeniſh yellow, with a faint muſky ſmell. Anthers ferruginous[6].

Native of many parts of Europe; Sweden, Denmark, Lapland, England, Germany, Switzerland, Auſtria, Pruſſia, Italy, &c. With us near Enfield in Middleſex; chalk-pits near Gogmagog hills in Cambridgeſhire; Marham near Swaffham, and near Snettiſham in Norfolk. It flowers in july.

16. The root conſiſts of two roundiſh bulbs, (and not of one rooting at bottom, as in *paludoſa*, *monophyllos*, and *Monorchis*), rooting at top. Root-leaves generally four, filiform, awl-ſhaped, an inch long. Stem naked, the length of the leaves. The ſpike conſiſts of four or five alternate flowers. Petals five, converging: beard ovate-oblong, entire, ſcarcely longer than the petals. Two ſheaths inveſt the baſe of the plant, and incloſe the leaves with the ſcape at the bottom[1].

Native of the mountains of Lapland, Denmark, Switzerland, Dauphiné, Piedmont, Carniola, Auſtria, &c.

17. Native of Siberia.

18. Stem about a foot high, firm, ſmooth, round at the baſe, ſomewhat angular upwards. Root-leaves four or five, ſheathing the ſtem at the baſe, lanceolate but varying in breadth, ſpreading: above theſe one or two more, cloſely embracing the ſtem. Flowers numerous, in a long looſe ſpike. Bractes membranaceous, lanceolate, awned, half as long as the germ. Petals converging; the three outer ovate-lanceolate, greeniſh with purple lines and margins; the two inner linear: lip of the nectarium long, dependent, yellow, divided into three lobes, the two outer half as long as the middle one, linear and ſlender; the middle lobe divided again half way into two acute ſomewhat divaricated ſegments[2].

It varies in ſize, and in the colour of its flowers, from yellow green to bright ferruginous. The root, and indeed the whole plant, emits a ſtrong odour[3]. The flowers vary in number from ten to fifty. Germs oblong, ſeſſile[4], round, green, twiſted. Petals cloſing ſo as to form a hood. A little below the ſtigma, which is deeply hollowed out, are two pellucid ſhining glands, very conſpicuous. The filaments are very ſhort[5]. The lip of the nectary is ſo divided as to bear a coarſe reſemblance to the human arms and legs, whence old authors named it the Man Orchis.

Native of the ſouthern parts of Europe, and England. With us principally in dry paſtures and old chalk-pits; in ſuch ſituations it is one of the moſt common of the tribe in Kent, as near Northfleet, Greenhithe, between Graveſend and Cliffe, Dartford, Bocton church-yard, and in the way to Branley, Trunhill, &c. In Surry about Croydon and Leatherhead. Near Linton in Cambridgeſhire. Kimbolton

in Huntingdonſhire. Dalington near Sudbury in Suffolk. Athwelthorpe near Norwich. It flowers in june.

19. Dr. Smith ſuſpects this to be a variety of O. apifera, perhaps inaccurately drawn [a].

20. Stem a foot high. Stem-leaves embracing, ovate, oblong, acuminate, nerved. Spike oblong, many-flowered, the flowers diſtant. Firſt petal between the following, lanceolate, erect: ſecond and third upper, outer, obovate, erect: fourth and fifth ovate, concave, reflex, much ſhorter than the former: lip triangular, ſagittate; the leſs above the ſtamens, before the firſt petal; the largeſt obcordate, ſubpedicelled.—Native of the Cape of Good Hope.

21. Stem a ſpan high. Root-leaves ovate, nerved: ſtem-leaves ovate-oblong, ſeveral. Spike many-flowered, cloſe, mixed with bractes longer than the flower, ovate, ſpreading: upper petal roundiſh, arched; lip ſhorter, three-lobed.—Native alſo of the Cape [b].

22. Stem ſimple, a hand high. Leaves ſcattered, half embracing, numerous, wider towards the baſe, towards the top long-awl-ſhaped or linear. Spike terminating. Flowers ſeſſile, remote; under each a briſtle-ſhaped bracte the length of the flower. Petals ovate or lanceolate, obtuſe. Arch of the ſtamens of the ſame length with the petals, terminated by two erect linear parallel horns. The whole plant in drying becomes black.—Native of the Cape [c].

23. Scape a foot high. Leaves three, alternate, embracing, lanceolate; the root-leaves ſhorter. Raceme four or five-flowered. Bracte the length of the corolla: helmet one-leafed; the two lateral petals lanceolate, ſpreading: lip ſmall, lanceolate, bent in under the helmet with the lateral ſegments ſpreading very much, widening at the baſe with a lobe on each ſide.

24. Bulb roundiſh. Leaves lanceolate. Spike five-flowered or thereabouts, with ventricoſe bractes. Helmet very much arched, hemiſpherical, mucronate at top; the two wings ſpreading, two-lobed, the upper lobe larger: lip of the nectary erect, trifid, the middle ſegment acute, the lateral ones membranaceous, lineaf.

25. Scape a foot high, even, leafy. Leaves three or four, alternate, lanceolate. Flowers in a raceme, three or four, yellow.—Theſe are all natives of the Cape of Good Hope [d].

26. Stem a ſpan or a foot high. Leaves alternate, many (about ſixteen) over the whole ſtem, lanceolate-ſubulate, ſheathing with a wider baſe. Spike corymbed, without a diſtinct peduncle. Germ ſtreaked. The three upper petals nearly equal, ovate, uppermoſt arched, ſide ones ſpreading, the two lower ſide ones inſerted into the piſtil, thickiſh, oblong, blunt, ſmaller than the former petals: lip thickiſh, reſembling the lower ſide-petals, lanceolate.

27. Stem a ſpan high and more. Stem-leaves three, the firſt obſolete, the ſecond oval-lanceolate, the third ſpathe-form. Spike few-flowered, with ovate, acute bractes. The firſt petal lanceolate, concave, the ſecond and third very wide, roundiſh, the length of the firſt, the fourth and fifth ſemicordate, acuminate, of the ſame length: lip from the piſtil itſelf, ſmaller, ovate-lanceolate, waved.

28. Stem hardly a hand high, longitudinally imbricated with leaves. Root-leaves ſhort, linear. Stem-leaves ſheathing, awl-ſhaped, acuminate. Flowers two to four, rather large. Firſt petal cordate, acute, ſecond and third minute, oblong, under the firſt; fourth and fifth ſemicordate, ſublanceolate, the length of the firſt, ſpreading: lip ſubcapillary, linear, very ſhort.

All theſe are alſo natives of the Cape of Good Hope [e].

29. Leaves ſubradical, alternate, with a grooved, many-angled ſheath, acute, waved, concave, grooved, ſtreaked, entire, ſmooth, erect, a hand in length, two inches wide, three, four or five in number. Scape ſurrounded with leaves at the baſe, with acute angles, ſmooth, erect, longer than the leaves. Flowers at the top of the ſcape elongated, in a ſpike, alternate, drooping, purple. Spike ſharply angular, erect, ſmooth, about a ſpan in length. Perianth three-leaved, the two upper ſegments lateral, and one lower horizontal; they are equal, linear, and bent back on the edges and at the tip. Corolla three-petalled: uppermoſt petal ovate, jointed and reflex in the middle, having two calluſes at the baſe, grooved, emarginate, forming a hood or helmet, twice as wide as the reſt; the two lower lateral, bent down at the baſe, then bent back, linear, like the leaflets of the calyx, and of the ſame length: two calluſes at the baſe of the uppermoſt petal between the petal and the ſtyle. Anthers two, ſeſſile, under the top of the ſtigma. Style ſemicylindrical, curved towards the upper petal, a line in length, white. Stigma blunt. Capſule cylindric-triſorm, twiſted, erect, drooping at top, ſmooth, purple, half an inch long. Under each flower a very ſhort, ovate, purple bracte.

Native of Japan near Oſacca and Jedo; flowering in may and june. Its name in Japoneſe is Gin Ran [f].

30, 31, 32. Natives of the Cape of Good Hope [g].

33. Native of New Caledonia.

34. Native of New Zealand [h].

PROPAGATION AND CULTURE.

1. This plant refuſes culture, but may be tranſplanted from the places where it grows naturally into a ſhady part of the garden, where, if the roots are not diſturbed, it will continue many years, and flower, but not increaſe. The beſt time to remove the roots is in july or auguſt, when the leaves are decaying; for it will be difficult to find the roots after the leaves are gone.

[2. This may be treated in the ſame manner.

3. Is ſeldom cultivated in gardens, but not being nice in its ſoil or ſituation, grows more readily in a garden than moiſt of the Orchis tribe [i]. Johnſon however ſays he could not get them to grow in a garden, and that none of the Satyrions love to be pent up in ſuch ſtrait bounds [k].

5. Common Twayblade growing naturally in woods and thickets, will proſper very well in any ſhady part of a garden, eſpecially in a moiſt ſoil.

7, 8, 9. Require to be planted in bog earth, in a moiſt ſhady border, or in pots with bog moſs and earth, ſet in pans of water.]

12, 13, 14, 15, 18. All theſe may be preſerved in gardens, though not propagated there. The beſt time to remove the roots from the places where they naturally grow, is juſt before the ſtalks fall, for at that time they may be eaſily diſcovered, and are beginning to reſt, ſo that the bulb will be fully formed for flowering the following year, and will not ſhrink: but when they are removed at the time when they are in action, the bulb deſigned for flowering the following year, not being fully ripened, will ſhrink, and frequently periſh.

When they are removed into a garden, the ſoil ſhould be adapted to the ſorts. Such as grow in moiſt paſtures ſhould be planted in ſhady moiſt borders; thoſe which are inhabitants of woods may be planted under trees; but ſuch as grow upon chalk-hills ſhould have a bed of chalk prepared for them in an open ſituation; and when they are fixed in their ſeveral places, they ſhould not be diſturbed: for provided they are kept clean from weeds, the leſs the ground is diſturbed, the better the plants will thrive, and the longer they will continue.

[Theſe plants were cultivated with great ſucceſs by the late Peter Collinſon, Eſq. whoſe memory is revered by every botaniſt, in his garden at Mill-hill. His method was to place them in a ſoil and ſituation as natural to them as poſſible, and to ſuffer the herbage to grow round them [l]. They are commonly taken up with a large ball of earth and the graſs, &c. in which they grow, when they are coming in flower, or at leaſt when they are puſhing up their flowering-ſtem in ſpring, ſo that the ſpecies may be diſtinguiſhed:

[a] Tour. 2. 295. [b] Linn. ſuppl. [c] Linn. mant. [d] Linn. amoen. [e] Linn. ſpec. [f] Thunberg. [g] Thunb. cap. [h] Forſter. [i] Curtis. [k] Ger. emac. 219 [l] Curtis, lond.

in this ſtate they ſeldom continue in a garden more than one year, or at moſt two years, ſo that by this means vaſt quantities of theſe beautiful flowers are deſtroyed annually.

Mr. Curtis remarks, that he has not yet heard of theſe plants being propagated by ſeed; and that it is to be wiſhed ſome intelligent gardener would exert himſelf in making ſome experiments to raiſe them in this way.—They produce abundance of ſeed, and there can be no doubt of their increaſing by ſeed in their natural ſtate of growth.

14. With a little attention and management this plant will grow and flower more freely than many of the tribe. Mr. Curtis has found the following method ſucceſsful: take up the roots carefully when in flower, bare them no more than is neceſſary to remove the roots of other plants, fill a large-ſized garden-pot with three parts choice loam moderately ſtiff, and one part chalk mixed well together, and paſſed through a ſieve ſomewhat finer than a common cinder-ſieve; in this mixture place your roots at about the depth of two inches, and three inches apart, water them occaſionally during ſummer, if the weather prove dry; at the approach of winter place the pot in a frame under a glaſs, to keep it from wet and froſt, which combined deſtroy the beauty of the foliage, if not the plant itſelf; in the autumn, before any of the others make their appearance, this ſpecies emerges*.

ORCHARD. In planting an Orchard, great attention ſhould be paid to the nature of the ſoil; and ſuch ſorts of fruits only ſhould be choſen, as are beſt adapted to the ground deſigned for planting, otherwiſe there can be little hopes of their ſucceeding; and it is for want of rightly obſerving this method, that we ſee in many countries Orchards planted, which never arrive to any tolerable degree of perfection, the trees ſtarving; and their bodies either covered with Moſs, or the bark cracked and divided, both which are evident ſigns of the weakneſs of the trees; whereas, if inſtead of Apples the Orchard had been planted with Pears, Cherries, or any other ſort of fruit better adapted to the ſoil, the trees might have grown very well, and produced great quantities of fruit.

As to the poſition of the Orchard, (if you are at full liberty to chuſe) a riſing ground, open to the ſouth-eaſt, is to be preferred; but I would by no means adviſe planting upon the ſide of a hill, where the declivity is very great; for in ſuch places the great rains commonly waſh down the better part of the ground, whereby the trees would be deprived of proper nouriſhment; but where the riſe is gentle, it is of great advantage to the trees, by admitting the ſun and air between them, better than it can upon an entire level; which is an exceeding benefit to the fruit, by diſſipating fogs and drying up the damps, which, when detained amongſt the trees, mix with the air and render it rancid: if it be defended from the weſt, north, and eaſt winds, it will alſo render the ſituation ſtill more advantageous, for it is chiefly from thoſe quarters that fruit-trees receive the greateſt injury; therefore, if the place be not naturally defended from theſe by riſing hills, which is always to be preferred, then you ſhould plant large growing timber-trees at ſome diſtance from the Orchard, to anſwer this purpoſe.

You ſhould alſo have a great regard to the diſtance of planting the trees, which is what few people have rightly conſidered; for if you plant them too cloſe, they will be liable to blights; the air being hereby pent in amongſt them, will alſo cauſe the fruit to be ill taſted, having a great quantity of damp vapours from the perſpiration of the trees, and the exhalations from the earth mixed with it, which will be imbibed by the fruit, and render their juices crude and unwholeſome.

Wherefore I cannot but recommend the method which has been lately practiſed by ſome particular gentlemen with very good ſucceſs, and that is, to plant the trees fourſcore feet aſunder, but not in regular rows. The ground between the trees they plough and ſow with Wheat and other crops, in the ſame manner as if it were clear from trees; and they obſerve their crops to be full as good as thoſe quite expoſed, except juſt under each tree, until they are grown large, and afford a great ſhade; and by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, ſcarcely ever having any Moſs, or other marks of poverty, and will abide much longer and produce better fruit.

If the ground in which you intend to plant an Orchard has been paſture for ſome years, then you ſhould plough in the green ſward the ſpring before you plant the trees; and if you will permit it to lie a ſummer fallow, it will greatly mend it, provided you ſtir it two or three times, to rot the ſward of Graſs, and prevent weeds growing thereon.

At Michaelmas you ſhould plough it pretty deep, in order to make it looſe for the roots of the trees, which ſhould be planted thereon in October, provided the ſoil is dry; but if it be moiſt, the beginning of march will be a better ſeaſon. The diſtance, if deſigned for a cloſe Orchard, muſt not be leſs than forty feet, but the trees planted twice that diſtance will ſucceed better.

When you have finiſhed planting the trees, you ſhould provide ſome ſtakes to ſupport them, otherwiſe the wind will blow them out of the ground; which will do them much injury, eſpecially after they have been planted ſome time; for the ground in the autumn being warm, and for the moſt part moiſt, the trees will very ſoon puſh out a great number of young fibres; which, if broken off by their being diſplaced, will greatly retard the growth of the trees.

In the ſpring following, if the ſeaſon ſhould prove dry, you ſhould cut a quantity of green ſward, which muſt be laid upon the ſurface of the ground about their roots, turning the graſs downward, which will prevent the ſun and wind from drying the ground, whereby a great expenſe of watering will be ſaved; and after the firſt year they will be out of danger, provided they have taken well.

Whenever you plough the ground betwixt theſe trees, you muſt be careful not to go too deep amongſt their roots, leſt you ſhould cut them off, which would greatly damage the trees; but if you do it cautiouſly, the ſtirring the ſurface of the ground will be of great benefit to them; though you ſhould obſerve, never to ſow too near the trees, nor ſuffer any great rooting weeds to grow about them, which would exhauſt the goodneſs of the ſoil, and ſtarve them.

If after the turf which was laid round the trees be rotted, you dig it in gently about the roots, it will greatly encourage them.

There are ſome perſons who plant many ſorts of fruit together in the ſame Orchard, mixing the trees alternately; but this is a method which ſhould always be avoided; for hereby there will be a great difference in the growth of the trees, which will not only render them unſightly, but alſo the fruit upon the lower trees ill taſted, by the tall ones overſhadowing them; ſo that if you are determined to plant ſeveral ſorts of fruit on the ſame ſpot, you ſhould obſerve to place the largeſt growing trees backward, and ſo proceed to thoſe of leſs growth, continuing the ſame method quite through the whole plantation; whereby it will appear at a diſtance in a regular ſlope, and the ſun and air will more equally paſs throughout the whole Orchard, that every tree may have an equal benefit therefrom; but this can only be practiſed upon good ground, in which moſt ſorts of fruit-trees will thrive.

The ſoil of your Orchard ſhould alſo be mended once in two or three years with dung, or other manure, which will alſo be abſolutely neceſſary for the crops ſown between; ſo that where perſons are not inclinable to help their Orchards, where the expenſe of manure is pretty great, yet, as there is a crop expected from

* Curtis, Bond. n. 68.

from the ground beſides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an Orchard, you ſhould always obſerve to procure them from a ſoil nearly a-kin to that where they are to be planted, or rather poorer; for if you have them from a very rich ſoil, and that wherein you plant them is but indifferent, they will not thrive well, eſpecially for four or five years after planting; ſo that it is a very wrong practice to make the nurſery where young trees are raiſed very rich, when the trees are deſigned for a middling or poor ſoil. The trees ſhould be alſo young and thriving, for whatever ſome perſons may adviſe to the contrary, yet it has always been obſerved, that though large trees may grow and produce fruit after being removed, they never make ſo good trees, nor are ſo long lived, as thoſe which are planted while young.

Theſe trees, after they are planted out, will require no other pruning, but only to cut out dead branches, or ſuch as croſs each other, which render their heads confuſed and unſightly: the pruning them too often, or ſhortening their branches, is very injurious; eſpecially to Cherries and ſtone-fruit, which will gum prodigiouſly, and decay in ſuch places where they are cut; and the Apples and Pears which are not of ſo nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak ſhoots, whenever their branches are thus ſhortened; and many times the fruit is hereby cut off, which, on many ſorts of fruit-trees, is firſt produced at the extremity of their ſhoots.

It may, perhaps, ſeem ſtrange to ſome perſons, that I ſhould recommend the allowing ſo much diſtance to the trees in an Orchard, becauſe a ſmall piece of ground will admit of very few trees when planted in this method; but if they will pleaſe to obſerve, when the trees are grown up, they will produce a great deal more fruit, than twice the number when planted cloſe, and will be vaſtly better taſted; the trees when placed at a large diſtance, being never ſo much in danger of blighting, as in cloſe plantations, as has been obſerved in Herefordſhire, the great county for Orchards, where they find, that when Orchards are ſo planted or ſituated, that the air is pent up amongſt the trees, the vapours which ariſe from the damp of the ground, and the perſpiration of the trees, collect the heat of the ſun, and reflect it in ſtreams ſo as to cauſe what they call a fire-blaſt, which is the moſt hurtful to their fruits; and this is moſt frequent where the Orchards are open to the ſouth ſun. But as Orchards ſhould never be planted, unleſs where large quantities of fruit are deſired, ſo it will be the ſame thing to allow twice or three times the quantity of ground; ſince there may be a crop of grain of any ſort upon the ſame place (as was before ſaid,) ſo that there is no loſs of ground; and for a family only it is hardly worth while to plant an Orchard, ſince a kitchen-garden well planted with eſpaliers, will afford more fruit than can be eaten while good, eſpecially if the kitchen-garden be proportioned to the largeneſs of the family; and if cyder be required, there may be a large avenue of Apple-trees extended croſs a neighbouring field, which will render it pleaſant, and produce a great quantity of fruit; or there may be ſome ſingle rows of trees planted to ſurround fields, &c. which will fully anſwer the ſame purpoſe, and be leſs liable to the fire-blaſts before mentioned.

[Orchards in general are ſmall incloſures adjoining to a houſe, planted without much regard to ſoil or aſpect, merely for the convenience of ſituation in protecting the fruit. But in the cyder-counties, and particularly in Herefordſhire, they are diſperſed over all parts of the country, in various degrees of elevation, and in aſpects that look to every point of the compaſs: the ſouth-eaſt however, with a ſcreen to the north, ſeems to be the favourite aſpect. This has reaſon on its ſide; where however fruit-plantations are conſiderable, it may be prudent to have them in different aſpects; and Mr. Marſhall obſerves that in the year 1783 Orchard-fruit was cut off in every aſpect except the north-weſt. This probably was owing to the bloſſoms being kept back till froſt and blight were paſt, but there can be little doubt that on ground gently inclining to the ſouth or ſouth-eaſt, and well defended to the north and eaſt, there will be in general a greater probability of a crop, and the fruit will be better flavoured. The richeſt ſoil is commonly in vallies, and they are the moſt ſheltered from ſtorms; but they are alſo more ſubject to ſpring froſts, inſects and blights.

The beſt Orchards of Apples are on a ſtrong clayey ſoil, which is congenial to moſt varieties of this fruit; ſome of them however affect a light ſandy loam, as the Stire, Hagloe Crab, and Golden Pippin; and it is a fact well aſcertained, that cuttings from the ſame tree, and grafted upon ſimilar ſtocks, will produce Cyder of a different quality, when planted in different ſoils. It ſeems to be admitted that the liquor produced from trees in clay is of a ſtronger body, and will keep better than that which is made from trees on a ſandy ſoil.

Pears are leſs difficult in their ſoil than Apples, and are not ſo liable to be injured by froſt and blight. They are generally ſuppoſed to flouriſh moſt in a calcareous ſoil; the Squaſh however draws the fineſt Perry from deep ſtrong land.

Stocks for grafting upon are raiſed by ſowing either in november or february, the muſt or reſidue of Apples or Crabs after the cyder or vinegar has been ſqueezed out. It is ſown on a bed of highly cultivated mould, in a garden, and is kept clean by hand. If new varieties or the improvement of old ones be the object, the ſeed-bed ought to be made as rich as poſſible; but if the preſervation of varieties be all that is wanted, a common loamy ſoil is ſufficient.

This method of ſowing the muſt is a bad one, becauſe the largeſt and beſt kernels are bruiſed in the preſs, and thus the ſtocks are moſtly raiſed from the ſmaller ones. It would ſurely be better to pick a few of the beſt Apples from the tree, or rather to let them remain till they are ſo ripe as to drop off themſelves, and to take out the moſt ſound and healthy kernels.

Indeed ſtocks raiſed from apple-kernels are much inferior to ſuch as are raiſed from the Crab. The tree will bear fruit three or four years ſooner, but the Crab ſtock will endure twenty or thirty years longer, and is not ſo liable to moſs and canker.

At the end of two years the ſeedlings are planted out in the nurſery in rows, three feet diſtant, and from fifteen to eighteen inches, or even two feet aſunder in the rows; care being had not to cramp the roots, but to bed them evenly in the mould. The plants ſhould be ſorted, according to their ſtrength, the tap-roots taken off, and the longer ſide rootlets ſhortened. Whilſt they remain in the nurſery, which they generally do till they are finally planted out in the Orchard, they are trimmed twice a year. It is a good method to retranſplant them two years before they are to be transferred to the Orchard, into freſh unmanured ground, double dug, and ſet in a quincunx order, four feet apart every way. For raiſing or improving varieties the ſoil ſhould be deep and good; and the plants ſhould be moved every ſecond, third or fourth year. But all this trouble is ſeldom or ever taken.

While the plants are ſmall, the intervals may be cropped with ſuch kitchen-garden produce as will not overſhadow them or exhauſt the ground.

In trimming or pruning, if there be two leaders, the weaker ſhould be taken off: if the leader be irrecoverably loſt, cut the plant down to within a hand's breadth of the ſoil, and train a freſh ſtem. Take the undermoſt boughs off by degrees, always preſerving ſufficient heads to draw up the ſap: not trimming them up to naked twigs, as is the common practice, thereby drawing them up tall and feeble.

The length of ſtem to which ſtocks are uſually trained is ſix feet, or ſometimes near ſeven; if they were ſtill higher they would be more out of the reach of ſtock, and be much leſs injurious to whatever grows under it. The uſual ſize at which ſtocks of the common height are planted out, is four to ſix inches girt at three feet high; a ſize which they will reach, with proper management, in ſeven or eight years.

In planting the Orchard, the proper diſtance ought to be proportionable to the natural growth or ſpread of the trees. In old Orchards the trees are only eight or even ſix yards aſunder, the more prevailing diſtance now ſeems to be ten yards, twelve yards or half a chain might perhaps be ſtill better. In the graſs grounds of Glocesterſhire, and the arable fields of Herefordſhire, twenty yards is a common diſtance, ſome have intervals of twenty-five yards: a chain's length, or twenty-two yards, might be taken as a good medium diſtance. In this caſe, each acre would have ten, in that forty trees.

In grounds, the trees ſhould be in lines, for the convenience of ploughing. In cloſe Orchards they ſhould be ſet in the quincunx manner.

The time of planting is October and November, or February, March and April. Where the ſoil is dry and light, autumn is preferable; but in a cold wet ſituation, and tenacious ſoil, the ſpring months are beſt.

The leader ſhould now be ſhortened, and the ſmaller ſide-boughs taken off; leaving a proper choice of the larger ſide-boughs entire, and untouched, to draw up the ſap, and to furniſh wood proper for grafting.

The common method of planting is to dig a hole wide enough to receive the roots, which being placed within it, the mould is returned upon them in the order in which it came out, carefully replacing the ſods on the ſurface, that no graſsing ground may be loſt.

A better method is this: the ground being ſet out with ſtakes driven in the centres of the intended holes, deſcribe a circle five or ſix feet in diameter round each ſtake. If the ground be in graſs, remove the ſward in ſhallow ſpits, placing it on one ſide of the hole. Place the beſt of the looſe mould by itſelf on another ſide, and the dead earth in a third heap. Where the ſubſoil is cold and retentive, the holes ſhould not be made much deeper than the cultivated ſoil. In a dry light ſoil, the holes ſhould be made deeper, both to obtain a degree of coolneſs and moiſture, and to eſtabliſh the plants firmly in the ground. In ſoils of a middle quality, the hole ſhould be of ſuch a depth, that when the ſods are thrown to the bottom of it, the plant will ſtand at the ſame depth in the Orchard as it did in the nurſery. The holes ought to be made previous to the day of planting. If the ground and weather be dry, the holes ſhould have two or three pailfuls of water thrown into each the evening before.

In planting, the ſods ſhould be thrown to the bottom of the hole, chopt with the ſpade, and covered with ſome of the fineſt of the mould; if, with this, the bottom be not raiſed high enough for the plant, return ſome of the worſt mould before the ſods are put in. Upon the fine mould ſpread the loweſt tier of roots, drawing them out horizontally, with all their fibres, preſſing them evenly into the ſoil, and covering them, by hand, with ſome of the fineſt of the mould: one perſon ſteadying the plant, another adjuſting and bedding the roots, and a third ſupplying the mould; which being raiſed high enough to receive another tier of roots, they are to be ſpread and bedded like the former; thus proceeding till the roots are all bedded freely, yet firmly, among the beſt of the ſoil. When they are covered ſome depth, preſs the earth in well with the foot, and raiſe the remainder into a hillock round the ſtem, to afford coolneſs, moiſture and ſtability to the plant. It is a common fault to plant fruit-trees too deep in the ground. Provided they withſtand the violence of the wind, they can ſcarcely be planted too near the ſurface.

Young trees are frequently planted in hop-grounds, and therefore want no proteCtion; the land not being converted either into arable or paſture, till the trees are out of the reach of cattle. But when they are planted in paſture land or open fields, tall thorns faſtened by withes are commonly placed round them; this however is a fleeting guard, and the thorns are apt to rinſe the ſtem of the tree. The moſt effectual, but the moſt expenſive guard, is compoſed of four poſts put down in a ſquare, with rails mortiſed into them; to be effectual, the poſts ſhould be put at ſuch a diſtance and height, and the rails ſo cloſe, that cattle cannot reach the tree; the poſts alſo ſhould be ſet ſlanting outwards, that the area of the fence be wideſt at top: this fence occupies much land. Others ſet only three poſts, in a triangle, connected by rails as before. In both caſes care ſhould be taken that the lower rails are near enough to prevent ſheep from creeping through, for they, eſpecially when ſnow is on the ground, will bark the young trees.

The plantation will require copious watering the firſt ſummer, if the ſeaſon ſhould prove dry. The ſurface over the roots ſhould be kept free from graſs and weeds, and in a looſe pulverized ſtate, to induce the roots to ſpread horizontally on every ſide.

In Herefordſhire, the ſoil of Orchards is generally kept under tillage; in Glocesterſhire, in graſs. Either practice has its diſadvantages. Fruit trees, when fully grown, eſpecially if they are of a ſpreading growth, and are ſuffered to form drooping branches, are very injurious to arable crops, at leaſt in our moiſt climate: their roots, their drip, and their ſhadows are deſtructive, not to corn only, but to clover and turneps: they alſo impede a free circulation of air, and are in the way of plough-teams. Tillage however is favourable to the growth of young trees. Whereas in graſs grounds their progreſs is comparatively ſlow, for want of earth being ſtirred about their roots, and by being injured by grazing ſtock. Hence we may conclude, that where circumſtances will allow, it is beſt to plant fruit-trees upon a newly broken up ſward, to keep the ſoil under a ſtate of arable management, until the trees be well grown; then to lay it down to graſs, and let it ſo remain until the trees be removed and their roots decayed; when it will again require a courſe of arable management.

After Orchard trees are planted and fenced they have ſeldom any more care beſtowed upon them. Boughs are ſuffered to hang dangling to the ground, their heads are ſo loaded with wood as to be impervious to ſun and air, and they are left to be exhauſted by moſs and miſletoe.

By a redundancy of wood the roots are exhauſted unprofitably, the bearing wood is robbed of part of its ſuſtenance, and the natural life of the tree unneceſſarily ſhortened; whilſt the ſuperfluous wood endangers the tree, by giving the winds an additional power over it, and is injurious to the bearing wood, by retaining the damps, and preventing a due circulation of air.

The outer ſurface only is able to mature fruit properly; every inner and underling branch ought therefore to be removed. It is common to ſee fruit-trees with two or three tiers of boughs paſſing hand upon one another, with their twigs ſo intimately interwoven, that a ſmall bird can ſcarcely creep in among them. Trees thus neglected, acquire, from want of due ventilation, a ſtunted habit, and the fruit becomes of a crude inferior quality.

Miſſletoe is a great enemy to Apple Orchards, and is frequently permitted to be very injurious to them. The ordinary method of clearing trees from it, is to pull it out with hooks, in froſty weather, when being brittle, it readily breaks off from the branches. Sheep are as fond of it as they are of Ivy. A labourer could clean fifty or ſixty trees in one day, and yet the Herefordſhire Orchards are generally ſuffered to be exhauſted by this paraſite.

They are alſo very often almoſt entirely ſubdued by Moſs, which kills many trees, and injures others ſo much, that they are only an encumbrance to the ground and a diſgrace to the country. This evil may eaſily be checked, and to a great meaſure avoided. In Kent, there are men who make it their buſineſs to clean Orchard trees from Moſs, at a certain price by the tree or by the whole. Draining the land, if too retentive of moiſture, will ſometimes prevent or cure Moſs; or digging round the trees in winter, and bringing forth mould, or the ſcouring of ponds and roads, or the rubbiſh of old walls, well prepared and pulverized, and laid round the trees. Whatever contributes to the health of the tree, will cure or in ſome degree mitigate theſe and other diſeaſes.

When fruit-trees are hide-bound, they are ſcored,

by cutting the bark with the point of a knife, from the top to the bottom of the ſtem.

Spring Froſts are an enemy againſt which it is very difficult to guard Orchard trees. Dry Froſts are obſerved to have no other effects than keeping the bloſſoms back. But Wet Froſts, after rain or a foggy air, and before the trees have had time to dry, are very injurious, even to the buds. This cannot be avoided; much however may depend upon the ſtrength of the bloſſoms; and the aſſiſtance that art can give in this caſe is, to keep the trees in a healthy, vigorous ſtate, to enable them to throw out ſtrong buds and bloſſoms; and by keeping them thin of wood, to give them an opportunity of drying quickly, before the froſts ſet in.

Blights are very frequently fatal to the vernal bloſſoms, and the conſequent crop of fruit. Were it not for this malady, which commonly invades Orchards in May, many perſons think that there would be a crop of fruit every year as regularly as there is a crop of corn. Perhaps if trees in the full vigour of their life were to be kept in perfect order, and not ſuffered to overbear themſelves, this conſtant fertility might be looked for, if they were not attacked by natural evils; and perhaps theſe natural evils might be in ſome degree mitigated. But when trees are badly planted on an improper ſoil, are ill grafted on an infirm ſtock, have little care beſtowed on them, to protect them from cattle, and to keep them clean from Moſs and Miſſetoe, are ſuffered to run to unprofitable wood, and when they have a hit, as it is called, or bear a large crop of fruit, it is beaten down with poles or ſticks, by which the buds that are forming for the ſucceeding year are moſtly bruiſed or beaten off; is it any wonder, that with all this ill management, neglect and bad uſage, that the crop of fruit ſhould often fail, or that ſpring froſts and blights ſhould have their full effect upon trees ſo weakened and injured? it ſeems rather ſurpriſing, that inſtead of bearing once in two or three years, they ſhould ever bear at all.

The term Blight is vague, and no definite idea ſeems affixed to the term. Whether inſects be the cauſe or the effect of it, does not ſeem to be yet ſettled. It is aſſerted however, that if a mat or a piece of white paper be thrown over a tree at night, and examined in the morning, if there has been a blight, there will be little black ſpots, like the point of a pin. They ſeem lifeleſs, but if the ſun ſhine, by twelve o'clock they will be in motion. By next morning they will be gone from the mat, and then, and not till then, they go into the leaves of the trees, where they form neſts, and do the miſchief. In two or three days after the blight has infected an Orchard, the leaves of the trees will be curled. If the inſide be examined with a powerful microſcope, a thouſand ſmall inſects will be ſeen: theſe will ſeize upon the half-formed embryo, and deſtroy it in the midſt of its feeding leaves. If the bloſſom be not out, or the fruit formed, when theſe vermin arrive, they do no miſchief, but if the young fruit be juſt formed, and not of ſufficient ſtrength to repel their attack, it is ſo much the food they want, that it falls an immediate ſacrifice to their depredations. The critical period at which the fruit is ſubject to the mortality of the blight laſts only a few days: and therefore by having Orchards in different aſpects, there will be a great probability that one or other of them may eſcape it. All the aſſiſtance that art can render the trees againſt this evil is to keep them in a ſtate of health and vigour.

Smaller inſects are hurtful to the leaves, bloſſoms, and naſcent fruit. Larger inſects devour the fruit in a ſtate of maturity. Apples, particularly Cyder fruit, are of a texture firm enough to reſiſt their attacks: but Pears are devoured in great quantities ſome years by waſps. If a price were ſet in the ſpring upon the female waſp that comes out ſingly in May, it might be a means of deſtroying many neſts by anticipation *.

In Devonſhire Orchards are ſituated chiefly in vallies, and dips or hollows near houſes, not ſpread over the arable land and paſture grounds, as in Herefordſhire and Glouceſterſhire. Some of them lie bleakly expoſed to the north; others are in the current of the ſouth-weſt wind. But thoſe which ſucceed beſt are neither expoſed to the north eaſt, nor to the ſea winds from the weſt and ſouth-weſt.

The richeſt deepeſt loſs appear to have been choſen for Orchard grounds: the ſhallower ſoils are probably unfit for fruit-trees; but where ſituation will admit, ſuch as are encumbered with large ſtones, with good ſoil intervening, are ſingularly eligible.

Nurſery plants are ſingularly trained with ſtems not more than three or four feet high.

The ſame ground is kept in a ſtate of Orchard for a long continuance. As the old trees go off, young ones are planted in the intervals, without any apprehenſion of miſcarriage.

A ſtatute rod, namely five yards and a half, is the common diſtance between the trees. Some are not more than four yards apart, and a few are at ſix yards.

The moſt approved mode of planting is to remove the ſoil down to the rock, which ſeldom lies very deep, and to cover this eight or ten inches thick with a compoſt of freſh earth and ſea ſand; upon this they lay the inverted turf, and upon the turf the young tree is ſet, and its roots bedded in the beſt of the mould; finally covering them with the common earth raiſed in making the pit.

The uſual guard is brambles, bruſhwood or furze left till they rot at the foot of the tree.

During the winter months a Devonſhire Orchard appears as if hung with hoar froſt, owing to the white moſs, which hangs like ribbands from the boughs. Miſſetoe is not known there.

The uſe of the land is in a great meaſure thrown away. Horſes are ſuffered to run through it in winter, and calves are kept in it early in ſpring; but grown cattle and ſheep are at all times prohibited from entering; and whilſt the fruit is upon the trees, ſwine and even ſmall pigs are kept out; for in a bearing year the boughs bend to the very ground.

Previous to the gathering ſeaſon, the weeds, which are three or four feet high, are cut down with the ſcythe, and thrown to the roots of the trees, that the fruit may be found †.

In Kent, particularly about Maidſtone, are many ſmall incloſures, from one to ten acres, and ſomewhat more, planted with fruit of different kinds, for which the rocky ſoil of the neighbourhood ſeems particularly adapted. The beſt method known there for raiſing Orchards of Apples and Cherries, and plantations of Filberts is to plant them among Hops. The conſtant culture of the land for the Hops, with the warmth and ſhelter they afford the young trees, cauſes them to grow with great luxuriance. It is a very common practice to plant Hops, Apples, Cherries and Filberts all together. Eight hundred Hop-hills, two hundred Filberts, and forty Apple and Cherry trees to an acre. The Hops ſtand about twelve, and the Filberts about thirty years, by which time the Apple and Cherry trees require the whole land. Sometimes Apple and Cherry trees are planted in alternate rows, with two rows of Filberts between each row.

The method of planting Apple and Cherry trees, is to dig holes about two feet ſquare, and two ſpits deep, taking out the rock, and turning down the ſurface ſoil, on which the young tree is planted, and the remainder of the earth is trodden down cloſe about the roots. The trees are ſupported by ſtakes, until they get ſufficient ſtrength not to be hurt by gales of wind. A compoſition of lime and night ſoil is with a bruſh painted on their ſtems, which not only protects them from cattle, but is ſaid to promote the growth of them exceedingly.

The ſoil preferred for Cherries is a deep loam upon the rock. If grown by themſelves they are planted from twenty to thirty feet diſtant, and are put ſomewhat deeper in the earth than Apples: in other reſpects

* Marſhall's rur. econ. of Glouceſterſhire, &c. and Clark's ſurvey of Herefordſhire.

† Marſhall's rur. econ of the Weſt of England.

the management is the the fame *. Cherries feem to affect a calcareous foil, if we may judge from the fize and flourifhing ftate of the Black Cherry in the Chiltern part of Buckinghamfhire, on the almoft bare chalk rock.

In fome parts of Ireland it is a common practice, in planting Orchards for Apples, for making Cyder, to fet cuttings three or four feet long half way in the ground, of fuch forts as grow rough and knotty in the wood. They call them *ftitchers*: they rarely fail, and yield well and foon †.

On Pruning Orchards.

If pruning be judicioufly done, fruit trees will come into bearing fooner, and continue in vigour for nearly double their common age. No branch fhould ever be fhortened, unleſs for the figure of the tree, and then it fhould be taken off clofe at the feparation. The more the ranges of branches fhoot circularly, a little inclining upwards, the more equally will the fap be diſtributed, and the better will the tree bear. The ranges of branches fhould not be too near each other, that the fruit and leaves fhould all have their full fhare of ſun; and where it fuits, the middle of the tree fhould be ſo free from wood, that no branch croſſes another, but all the extremities point outwards.

October or November, or as ſoon as the fruit is off, is the proper ſeaſon for pruning. Few men cut true enough with a bill, it is therefore beſt to take off ſuperfluous branches with a ſaw, and afterwards to ſmooth the place with a knife; for it is eſſential that every branch which is to come off ſhould be cut perfectly cloſe and ſmooth. The wounds muſt then be fmeared over with a medicated tar. The bark cannot grow over a ſtump, becauſe there is no power to draw the ſap that way, for which reaſon always cut a little within the wood. Every branch ſhould be taken off that comes near to the ground, that has received any material injury, where the leaves are much curled, or that has a tendency to croſs the tree or run inwards. Then a little attention may be given to the beauty of the head, leaving all the branches as nearly equidiſtant as poſſible. If then there be any remaining blotches, open of ſcore them with a knife; and where the bark is ragged from any laceration, pare it gently down till you come to the live wood: touching over each with the medicated tar. This being done, the moſs ſhould be rubbed clean off, and the trees ſcored. In this laſt operation care ſhould be taken not to cut through the inner or white rind, which joins the bark to the wood. When trees are much thinned, they are ſubject to throw out great quantity of young ſhoots in the ſpring, theſe ſhould be rubbed off, and not cut, for cutting increaſes the number.

The medicated tar is compoſed of half an ounce of corroſive ſublimate, reduced to fine powder, by beating with a wooden hammer, and then put into a three-pint earthen pipkin, with about a glaſs full of gin or other ſpirit, ſtirred well together, and the ſublimate thus diſſolved. The pipkin muſt then be filled by degrees with vegetable or common tar, and conſtantly ſtirred till the mixture is intimately blended. This quantity will be ſufficient for two hundred trees. Being of a very poiſonous nature, it ſhould not be ſuffered to lie about the houſe. The ſublimate diſſolves better, when united with the ſame quantity of ſpirit of hartſhorn, or of ſal ammoniac.—This mixture being apt to run, conſiſtency may be given it by mixing pounded chalk or whiting.

Hints on Planting Orchard Trees, &c.

If poſſible, chooſe the trees the year before they are to be planted, and ſee that they are properly pruned in the nurſery, by taking off cloſe all rambling and unſightly branches, leaving only three or four good leading ſhoots; by this foreſight the trees will not require pruning for ſome time, and it will greatly accelerate their growth that they have no wounds to heal the year they are tranſplanted. Be ſure the trees are young, and plant no galled, ſtunted or cankered plants.

When the trees are taken up, keep the roots as long as is convenient, which will give them a diſpoſition to run horizontally, from which, the roots being more under the influence of the ſun, the ſap is richer, and produces the ſweeteſt fareſt fruit.

An Orchard ſhould be ſcreened on the eaſt, north and weſt ſides, and open to the ſouth. The natural growth of the different fruits ſhould be attended to in the diſpoſition of the trees. One row of the taſteſt ſtrongeſt growers ſhould be planted on the three cold ſides, and that row ſhould be planted twice as thick as any other: then one row more of the next free growers, parallel to the laſt rows, and ſo on gradually declining in ſize till you come to the centre. The intention here is to raiſe ſhelter; and it would be adviſeable, on the outſide of theſe outer rows, to run a ſhaw or belt of underwood, more than a pole wide, of four or ſix rows of the ſtreſt growing trees which the country produces; the wood of which will more than pay the expenſe. Half the trees ſhould be cut down in about fourteen years, to become ſtools, and the other half at a proper diſtance of time; ſo that the belt, for the whole duration of the Orchard, ſhall be of young wood, and feathering down to the bottom. Nothing can be better for this purpoſe than the ſweet Cheſtnut, where the ſoil ſuits it. The Hawthorn likewiſe, properly trained, has a wonderful good effect in blunting or abſorbing the baneful quality attendant upon the blighting air. Before the ground is laid out, be careful to ſecure the little rifings or inflections, to catch the ſun and exclude the cold. Firs may be happily introduced at a diſtance for ſhelter: all together might be ſo diſpoſed as at the ſame time to protect the fruit, and embelliſh the appearance of the country.

Such an Orchard may often bear a crop when the neighbourhood in general fails, and every one knows the value of a good crop in a failing year.

The plantations, belt and larger trees will keep off the blighting winds; and the Orchard being open in the middle and to the ſouth, the fragrant vapours which ſtun the fruits in the ſpring will be diſſipated, and each tree will enjoy the influence of the ſun and air. Beſides, the ground being open in the middle, the herbage will be the more valuable.

In new plantations avoid planting too deep, or too thick. Sunſhine will bring ſweet fruits; ſhade and plunging the roots beyond the influence of genial warmth will produce crude acid juices.

When the top of a tree ſeparates by the weight of the branches, an iron bolt may be introduced, by boring a hole through the upper part of the cleft with an half inch auger; firſt cutting the bark, and part of the wood with a chiſel, ſo as the head at one end, the nut and ſcrew at the other, may be hid under the bark. By uſing the medicated tar, the bark will ſoon grow over the iron.

The Orchardiſt's tools are two pruning-knives, a ſaw, two chiſels, a mallet, a ſpoke-ſhave, and a painter's brush. With the chiſels and ſpoke-ſhave work upwards, or the bark will ſhiver: the ſaw muſt be coarſe ſet, all the other tools ſharp and ſmooth.

The blade-bone of a ſhoe is better than the iron of the ſpoke-ſhave to rub off the rotten bark, moſs, &c. ‡

Mr. Marſhall recommends a young Orchard to be under the plough, as remarked above; whereas, according to Mr. Bucknall, if an Orchard be cultivated by the plough, little good can be expected, for the injuries which young trees receive from implements of huſbandry bruiſing them before they have got full poſſeſſion of the ſoil, generally damage them conſiderably, if they do not deſtroy them: and if by care they ſhould ſurmount theſe evils, the crops of corn being regularly carried off the land, the ground is ſo much impoveriſhed, that the trees are ſoon ſtunted, and run to moſs.

* Boys's Survey of Kent.

† Young's Irish tour, v. 336.

‡ The above obſervations on pruning, planting, &c. are from the Orchardiſt, by Thos. Skip Dyot Bucknall, Eſq. extracted from the Tranſactions of the Society of Arts.

There is not any culture we are acquainted with, equal to Hops, for raising an Orchard; and when the proper time comes for grubbing up the Hops, the trees may be secured, and the land turned to grazing. It would be better not to take up the Hops all at once, and to crop the vacant land for two or three years with Potatoes. Thus the trees would continue in better health, by taking away the shelter gradually. Let the agriculture be what it may, the land should never be ploughed or dug deep directly over the roots of a young-planted fruit-tree; for as the roots collect the best sap from their extreme points, if those points be broken off from the upper side of the roots, the tree is compelled to subsist on nurture drawn from the under strata, and consequently the sap will be of a worse quality.

Where hogs and poultry are constantly running over the ground, the trees seldom fail of a crop, which is the best proof that manure is necessary. Any manure will suit an Orchard; but the sweepings of cow-houses, hog-yards, slaughter-houses, dog-kennels, emptying of drains, &c. are more disposed to facilitate the growth and promote the health of fruit-trees, than manure from the stable. Watering, in dry weather, tends much to keep trees in health, and to secure their bearing, by swelling the buds for the next year's crop; for when the buds are strong at first coming out, they are not so liable to blight.

Those sorts of fruit which are known to thrive best in the neighbourhood should in general be preferred: and care should be taken not to suffer trees to bear much fruit whilst young.

Where trees are much overrun with mofs, a strong man, with a good birch broom, in a wet day, would do great execution. On young trees, the best method of destroying mofs is to rub all the branches, spring and autumn, with a hard scrubbing-brush and soap-suds, as a groom does a horse's legs.

Canker, in great measure arises from animalcules, and where the only object is to remove this disease, hog's-lard is preferable to tar; but where wet is to be guarded against, tar is better.

The best soil for an Orchard is certainly a fine deep loam; but if it is a strong clay, chalk, or a cold sharp gravel, plant the trees above ground, raising over them a little mound of good fresh mould as large as an extensive ant-hill, sowing the top with white Dutch Clover.

It is recommended that the rows of trees should not stand north and south, but a point of the compass towards the east; as the sun will then shine up the rows soon after ten o'clock, which in the spring will serve to dissipate the vapours collected in the night, and thus prevent the fruit from being stinted in the early stages of its growth *.

On Root-Pruning.

When a tree has stood so long that the leading roots have entered into the under strata, they are apt to draw a crude fluid, which the organs of more delicate fruit-trees cannot convert into such balsamic juices as to produce fine fruit. To prevent this evil, as soon as a valuable tree begins to show a sickly pinkeyness upon the leaves or the fruit inclining to ripeness, before it has acquired its full growth; at the same time the bark becoming dry, hard, and disposed to crack; let the ground be opened for three or four feet, and with a chisel cut close every root the least tending downwards. Should there be any mouldy appearance or rottenness among the roots, take them off, and wash the others clean. If the ground be too wet, throw a few stones or brickbats under the stem of the tree.

As the roots invariably collect the sap from the extreme points, this cutting compels the horizontal roots to work and exert themselves; and if there be any energy left, they will soon throw out fresh fibres, and thus collect a more congenial sap for the support of the tree. At the same time cover the ground thinly over with manure, as far as the roots may be supposed to extend, rub the stem and branches with soap-suds, and water the ground in very dry weather.

* Orchardist, by Dean Rocksall, Esq. p. 52. &c.

There is not a more powerful agent for producing canker than these descending roots. Canker indeed may arise from an improper soil, a vitiated sap, the generation of vapour, animalcules, and the want of a free circulation of the fluids: the last is often caused by injudiciously shortening the leading branches. The medication before recommended will stop the progress of the evil on the parts to which it is applied, but the canker may again break out on the other parts of the same tree; and that arises from the roots striking into a cold congenial subsoil †.

For a fuller account of some particulars relative to Orchards, here omitted, see NURSERY, PLANTING, PRUNING, and the articles under which Orchard trees are particularly treated of, as PYRUS and PRUNUS.

Class. 20. 1. Gynandria Diandria.

Nat. order of *Orchideæ*.

GENERIC CHARACTER.

CAL. *Spathes* wandering. *Spadix* simple. *Perianth* none.

COR. *Petals* five: three outer, two inner, converging upwards into a helmet.

Nectary one-leafed, fastened to the receptacle by the lower side between the division of the petals: *upper lip* erect, very short: *lower lip* large, spreading, wide: *tube* behind horn-shaped, nodding.

STAM. *Filaments* two, very slender, very short, placed on the pistil. *Authers* obovate, erect, covered with a bilocular folding of the upper lip of the nectary.

PIST. *Germ* oblong, twisted, inferior. *Style* fattened to the upper lip of the nectary, very short. *Stigma* compressed, blunt.

PER. *Capsule* oblong, one-celled, three-keeled, three-valved, opening three ways under the keels, cohering at the top and base.

SEEDS numerous, very small, like sawdust.

ESSENTIAL CHARACTER.

Nectary a horn or spur behind the flower.

SPECIES.

Helmet of the corolla spurred.

[1. Orchis carnea. *Great-flowered Cape Orchis.*
Ait. hort. kew. 3. 294.
Bulbs undivided, helmet of the corolla two-spurred, bractes erect.

2. Orchis bicornis. *Yellow-flowered Cape Orchis.*
Lin. spec. 1330. *Reich. 4. 4. amœn. 6. afr.* 90. *Burm. cent.* 3. 6. t. 6.
Bulbs undivided, helmet of the corolla two-spurred, lip five-parted, bractles reflex.

3. Orchis bifolia. *Two-flowered Orchis.*
Lin. spec. 1330. *Reich. 4. 4. amœn. 6. afr.* 92.
O. flexuosa. *Lin. syst.* 807. *suppl.* 398.
Bulbs undivided, helmet of the corolla one-spurred, wings spreading, lip lanceolate acuminate.

4. Orchis cornuta. *Horned Orchis.*
Lin. spec. 1330. *Reich. 4. 4. amœn. 6. afr.* 91.
Bulbs undivided, helmet of the corolla one-spurred, wings spreading, lip very small subrunate.

5. Orchis spathulata. *Spatulate Orchis.*
Lin. syst. 807. *suppl.* 398.
Bulbs undivided, helmet of the corolla spurred.

6. Orchis tripetaloides. *Three-petalled Orchis.*
Lin. syst. 807. *suppl.* 398.
Leaves lanceolate, helmet of the corolla arched blunt spurred, nectary lanceolate very small.

7. Orchis fagitalis.
Lin. syst. 807. *suppl.* 399.
Helmet of the corolla spurred two-eared, lip lanceolate.

† Orchardist, appendix.

8. Orchis barbata. *Bearded Orchis.*
Lin. syſt. 807. *ſuppl.* 399.
Helmet of the corolla erect ſpurred, nectary ſubtrifid ciliate.

9. Orchis draconis. *Dragon Orchis.*
Lin. syſt. 807. *ſuppl.* 400.
Bulbs undivided, helmet of the corolla ſpurred, nectary linear ovate at the tip.

10. Orchis tenella. *Delicate Orchis.*
Lin. syſt. 807. *ſuppl.* 400.
Helmet of the corolla ſpurred conical at the baſe, nectary linear.

11. Orchis monorrhiza. *One-bulbed Orchis.*
Swartz prodr. 118.
O. ſetacea? *Jacqu. amer.* 220.
Satyrium 1. *Brown. jam.* 324.
Bulb ſolitary undivided, lip of the nectary three-parted, the lateral parts briſtle-ſhaped, horn linear compreſſed the length of the germ.

** *Bulbs undivided.*

11. Orchis ſaneta. *Paleſtine Orchis.*
Lin. ſpec. 1330. *Reich.* 4. 4.
Bulbs undivided? lip of the nectary lanceolate five-toothed, horned curved in, petals converging.

12. Orchis ſuſannæ.
Lin. ſpec. 1330. *Reich.* 4. 4.
O. amboinenſis, flor. albis fimbriatis. *Herm. par. t.* 209. *Raii ſuppl.* 588.

Horn of the nectary recurved, lip ovol ſhaped entire.

50. Orchis falcata.
Lin. fysh. 811. *Thunb. jap.* 26.

Horn filiform very long, leaves enſiform-channelled ſickle-ſhaped.

DESCRIPTIONS, &c.

1. Leaves roundiſh, grooved underneath. Spike compact. Bractes roundiſh, acute, erect. Flowers inodorous, white within, fleſh-coloured without. The two uppermoſt petals and the loweſt narrower than the others, all keeled on the outſide, the keel running down into the germ, whence the germ is five-ribbed below. The column of the fructification is the length of the helmet. Found at the Cape of Good Hope by Mr. Francis Maſſon. It was introduced in 1787, and flowers in ſeptember.

2. Leaves ovate-oblong, marked with lines underneath. Spike looſe. Bractes ovate-lanceolate, reflex-

flowers very fragrant, ſmelling like cloves, yelloviſh green. The three lower petals narrower and ſhorter. Column of fructification ſhorter than the helmet [r].

Root-leaves two, cordate, oppoſite, ſtem-leaves three or four, alternate, cowled. Bractes the length of the ſpike. Helmet of the corolla one-leafed, arched, acuminate, larger: the two lateral petals a little wider: lip linear, with equal ſegments: body of the ſtyle oblong, curved inwards; with two rounded lobes under the tip [s]. This ſpecies is remarkable for its double ſpur, ariſing from the helmet inſtead of the lip [t].

Native of the Cape of Good Hope. Introduced in 1787, by Mr. Francis Maſſon. It flowers in ſeptember [u], and is extremely ſweet.

3. Root-leaves ovate, ſmall. Scape filiform, with three or four leafy ſheaths. Upper petal of the corolla ſhort, acuminate: ſpur aſcending, the length of the petal: the two inner petals linear, with two teeth at the tip, having a lobe underneath concealed beneath the upper one, and of the ſame length, embracing the genitals: lateral petals two, lanceolate, longer than the others [v].

Orchis flexuoſa of the ſupplement is ſaid to be the ſame with this. The ſcape is deſcribed as half a foot high, filiform, bent above the ſtem-leaf. Root-leaves ovate, acute, petioled. Stem-leaves ſmall, ſheathing at the baſe, lanceolate, three or four. Flowers from three to five in a raceme, remote, pedicelled. Upper petal lanceolate, riſing, with a ſpur the length of the flower: ſecond and third inner, ſhort, linear, with two teeth at the tip; fourth and fifth lanceolate, a little longer than the firſt: lip awl-ſhaped, with a tooth on each ſide at the baſe. Native of the Cape of Good Hope.

4. Leaves on the ſtem many, alternate, large, lanceolate, ſheathing at the baſe. Spike looſe. Bractes lanceolate, longer than the flower. Helmet arched, oblong, blunt: horn blunt, ſhort, lying on the germ: petals two, lateral, exterior, oblong, ſpreading; two interior, oblong, ſhorter than the helmet, fleſhy at the tip, thickiſh, almoſt converging beneath the helmet. Native of the Cape of Good Hope [w].

5. Root-leaves very many, linear, ſhorter by half than the ſtem. Scape a ſpan high, ſheathed: leaves acute, ſcarioſe, wider. Flowers generally two, alternate. Germ oblong, pedunculed, inferior. Helmet of the corolla pedicelled, very ſhortly ſpurred, cordate: the two lateral petals ovate, acuminate: lip cordate, on a filiform pedicel, twice the length of the flower. Native of the Cape of Good Hope [x].

6. Stem a foot high, even. Root-leaves ſeveral, a hand in length: ſtem-leaves alternate, about eight, an inch long, embracing. Spike many-flowered. Flowers alternate, diſtinct: firſt petal roundiſh, very much arched, with a very long conical horn behind; ſecond and third oblong, very ſhort, annexed to the genitals; fourth and fifth roundiſh, ſpreading, larger than the others; hence from the firſt, fourth and fifth, a ſort of three-petalled flower is formed: lip very ſmall, lanceolate, blunt. Found at the Cape of Good Hope by Thunberg [y].

7. Root-leaves four or five, ſhorter by half than the ſtem, lanceolate, bluntiſh. Stem a ſpan high, covered entirely with leafy, membranaceous, acute ſheaths. Spike ſhort. Firſt petal concave, with a ſagittate point, and two ſharp earlets turned back, and a ſhort horn behind: ſecond and third oppoſite to the genitals, very acuminate, wide at the baſe, not ſhorter than the uppermoſt: fourth and fifth, elliptic, the ſame length with the reſt [z].

8. Bulbs oblong, undivided, very hairy. Scape a foot high, leafleſs, the thickneſs of a ſparrow's quill. Leaves very many, briſtle-ſhaped or linear, ſome almoſt the length of the ſcape, others ſhorter. Uppermoſt petal ovate, with an erect ſpur behind. The neareſt lateral petals on each ſide, ovate-oblong, the ſize of the uppermoſt, ſpreading: the two neareſt interior petals very ſhort, by the ſide of the genitals. Lip lanceolate, branchingly ciliate: cilias blunt, the length of the flower. Germ recurved.

9. Scape a foot and half high, the thickneſs of a gooſe quill, wholly ſheathed with leaves. Root-leaves lanceolate, an inch wide, ſhorter by half than the ſcape: ſtem-leaves ſheathing, netted-veined, acute. Spike with few flowers, ſomewhat remote. Bractes broad-lanceolate, netted-veined, the length of the germ. Upper petal obovate, larger, ſomewhat arched, with a very long ſpur behind: lateral petals on each ſide two, lanceolate: lip linear with an ovate tip, the length of the petals.

10. Stem the length of the thumb or of Ophrys Monorchis. Leaves both on the root and ſtem linear. Spike oblong, with from five to eight flowers. Firſt petal ovate, horned behind with a conical baſe: ſecond and third converging under the firſt, and ſimilar to it: fourth and fifth lateral, ſpreading: lip linear.

All theſe were found at the Cape of Good Hope by Sparrmann [a].

11. Height from eighteen to twenty-two inches. Stem ſimple, upright. Leaves oblong [b]. Native of Jamaica and Hiſpaniola [c].

Swartz thinks it may poſſibly be the ſame with the *ſetacea* of Jacquin, which he deſcribes as two feet high and erect, with lanceolate acute entire alternate leaves, the flowers in a ſpike and white. It is a native of Martinico, in moiſt meadows, and flowers there in november [d].

11. Stem a foot high, for the moſt part naked, but having one or two ſharp leaflets at top. Raceme looſe. Bractes lanceolate, the length of the germ. Petals acuminate, three, uniting to form an oblong helmet, but diſtinct at the tip: lip wide-lanceolate, divided into five ſharp teeth, the intermediate ones gradually longer. Native of Paleſtine [e].

12. This is a very elegant ſpecies. Lower leaves ſhort, acuminate, embracing: upper longer, green, round, ſmooth. Stem a long ſpan or a foot high, ſlender. Flowers white: helmet entire, wide, roundiſh, with two fringed, ſpreading wings, and a long narrow lip: ſpur ſlender, very long [f]. Native of Amboina.

13. Stem round, ſtriated, ſheathed with leaves, erect, a ſpan high. Leaves alternate, ſheathing, enſiform, channelled, from erect ſpreading, ſtriated, ſmooth, nearly equal to the ſtem, the upper ones ſmaller, about five in number. Flowers alternate, about three, flowering ſucceſſively. Bractes lanceolate, acuminate, ſmooth, ſhorter than the capſule. Perianth three-leaved, equal, ſmooth, ſpreading, green: leaflets ovate, acuminate, concave, ſtriated. Corolla three-petalled, ſnow-white: the two upper petals equal, forming a helmet with the erect ſegment of the calyx, ovate, concave, with the outer margin flat; they are longer than the calyx: lower petal clawed, horned, plano-convex, three-parted: lateral ſegments dilated, ciliate, clawed, the middle ſegment lanceolate, entire, ſcarcely a line wide. Horn of the nectary cylindrical, in front, hanging down, greeniſh white, twice as long as the capſule. Anthers two, ſeſſile under the top of the ſtigma. Style very ſhort, thick. Stigma concave. Capſule ſubtrigonal, ſix-ſtriated, ſmooth, ſcarcely twiſted, half an inch long. Native of Japan: flowering in auguſt and ſeptember [g].

14. Stem tall, firm, having at the lower part two or three oblong, wide, liliaceous, embracing leaves, and ſome ſmaller leaves above. Spike not very long, compoſed of cluſtered flowers. Helmet ſmall and acute: lip hanging down forward, long, narrow, cut on both ſides into very narrow little jags, and as it were fringed: ſpur ſtretched out backward and very long: colour yellow [h].

It grows to two feet in height and more, with a ſtraight, ſtriated ſtem. The uppermoſt leaves are ſcarcely an inch in length and ſharp. Flowers pedicelled. Spur ſlender, an inch or more in length, recurved, hanging down. It was ſent by Baniſter from

Virginia [1]. Petiver informed Ray that it is of Maryland origin. Linnæus sets it down as a native of Virginia and Canada.

15. Bulb single, middle-sized, oblong, tomentose, with long, filiform, simple fibres above the bulb. Stem erect, leafy, from one to two feet high, simple, angular, smooth. Leaves sessile, alternate, sheathing at the base, ovate-lanceolate, acute, smooth and shining, three-nerved, netted-veined: sheaths closely surrounding the stem and smooth. Flowers in spikes, alternate, scattered, at a little distance, white. Among the flowers the stem is acute-angled. Spathes (bractes) under the flowers wide, keeled, three-nerved, smooth, green. Corolla five-petalled. Three petals exterior: the upper or middle one, which is the helmet, arched, erect, three-keeled, greenish white, smooth; two lateral somewhat turned back, ovate-lanceolate, keeled, green: two interior lateral, cloven at the base: the upper segments inclosed within the arched petal, of the same length; the lower segments filiform, much longer than the upper ones, spreading, white. Nectary behind under the helmet, arched; triangular in the middle, divided into cells at the sides, and in front divided into two long horns, between which a funnel-form passage opens into the horn of the germ. Filaments capillary, from the lateral cells of the nectary communicating by canals with the tips of the horns, and there glued to them. Anthers in the cells, filled with yellow globular pollen. Germ inferior, ellongated, three-sided, gibbous, hexangular. Style none. Stigma stretched out between the horns, behind the opening, convex, shining, mouthened. Lip of the nectary three-parted, inferted before the stigma and the horn of the germ: the middle segment lanceolate, acute, plano-convex; the lateral ones filiform, three times the length of the other, bent down: horn four or five times as long as the germ, roundish-compressed a little at the base, lanceolate at the end, and incipital, glued to the stem after flowering. Capsule large, three-winged, six-grooved, opening in the middle into six parts, cohering at the top. Seeds brittly. The flowers are very singular, and together with Orchis monorrhiza might perhaps constitute a separate genus.

Native of Jamaica in low meadows at the foot of the mountains [2].

16. Bulbs ovate, tapering to a point at the base, white within and without, thick fleshy fibres come out above them from the base of the stem [3]. One of these bulbs is always wrinkled and withered, whilst the other is plump and delicate. The first is the parent of the actual stem, the second is an offset, from the centre of which the stem of the succeeding year is destined to arise. Such is the mode of increase not only in this species, but in the other bulbed Orchises; and such are the means that nature uses not only to disseminate plants, but to enable them to change their place and thus to draw in fresh nutriment; for the second root is always about half an inch from the centre of the first, insomuch that in twenty years the plant will have marched ten inches from the place of its birth. The process is the same in the handed Orchises, or those species which have the bulbs divided and lengthened out like the fingers, and even in fibrous roots, for some of the fibres are continually rotting and perishing, whilst other young and tender ones are protruding, lengthening, increasing and preparing for the vegetation of the succeeding year. This mode of increase is particularly necessary in a family of plants that rises with great difficulty, and very seldom by seed [4]. We have no proof of the Orchis growing by seed, but we cannot account for the great increase of some of the species any other way. But to proceed with the description: stem a foot or eighteen inches high, smooth, six-angled, three ribs running down from each leaf. Leaves usually two, (sometimes three) springing from the root, ovate, blunt, tapering at the base, five or six inches long, and from two to three inches wide, smooth, pale green above, silvery beneath, marked with numerous parallel veins or nerves. On the stem are three or four lanceolate, sessile leaves, the lowest of which are longest. Flowers numerous in a long loose spike. Bractes lanceolate, acute, resembling the stem-leaves, much longer than the germ (of the same length according to Curtis, or a little longer as Pollich affirms; not longer than the germ, according to Scopoli.) Petals yellowish-white, or rather white with a tinge of green; the three exterior large, the middle one heart-shaped, obtuse, covering the hood, the two outer lanceolate, longer but narrower, patent and somewhat reflected, forming obtuse angles with the middle one: the two interior petals linear-lanceolate, small, converging over the hood, incurvated, so that their tips nearly touch, though the bases are distant: hood very open. Stamens bright yellow: anthers straw-coloured. Cases distant. Lower lip of the nectarium linear, narrow, entire, nearly as long as the germ, somewhat convex on the upper, and concave on the lower surface, whitish upwards, green towards the ends: horn almost as long again as the germ, slender, whitish upwards, the rest green, somewhat compressed, and broadest towards the end [5]. It is transparent, and shows the nectareous liquor with which it is often filled.—Retzius remarks, that there is no filamentous column properly so called, but a very large arched stigma, the cloven sides of which include the male parts: the stamens are entirely free, that is, not fastened to any thing, but concealed within the lateral cleft of the pistil, with the filament longer than the anther, furnished with a lateral petta vided towards the base.—Capsules ovate, triangular, yellowish, brown when ripe, smooth; having three longitudinal ligaments, which are loosened when the seeds are ripe; the seeds are then cast out through the longitudinal clefts; they are very minute and abundant [6].

This species has obtained the name of *bifolia*, on account of its radical leaves being usually two; three however are frequently met with: they are commonly said to be opposite, but they are not so strictly opposite as in *Ophrys ovata*. The English name of *Butterfly Orchis* is scarcely warranted by the appearance of the flower [7]: but some species of the order bearing a resemblance to bees and flies, the rest must needs be referred to some other animals. The smaller variety is named in Johnson's edition of Gerarde's herbal *Gnat Satyrion*. The flowers may be allowed to bear a general coarse resemblance to an insect; at least they approach it more nearly than those of *Ophrys anthropophora* and *Orchis militaris* do to the human figure.

Orchis conopsea having a very long spur or horn and spreading petals, as well as this species, Haller distinguishes it by the remoteness of the cells or cases in which the filaments are lodged.—It is obviously distinguished, says Mr. Curtis, by the colour of the corolla, the great length of the spur, (an inch long, widening at top and incipital) the delicious fragrance of its flowers, diffused chiefly in the morning and evening, and vying with that of the Honeysuckle, but above all by the unusual structure of its flowers: below the stigma, which is remarkably well defined in this species, there is a circular opening between the cavities containing the stamens, just above the stigma is a very conspicuous ridge, the cases containing the filaments are placed widely distant (as remarked above from Haller) and soon change to a brownish hue, the stamens are very loosely placed within them and drawn out with the slightest touch, the anthers are club-shaped and divided as in most others, the gland at the base of the filament is of a circular form, with a cavity on its inner side, and a kind of joint-like projection on its outer part.

The roots of this species being large, it appears to be as well calculated for making salep as any other.

This Orchis is not so common as some, is much more so than others, being found generally in woods, pastures and heaths, especially in soils somewhat stiff and moist. In dry pastures it is often so small as to be noticed for a variety [8]. It varies not only in size, but

[1] Mor. hist. [2] Swartz. [3] Woodw. Mss. and Pollich. [4] Villars. [5] Woodw. Mss. [6] Pollich. [7] Curtis. [8] Ibid.

in the shape and number of the leaves, the number of flowers, the length of the spur, and the time of flowering, which is later in the small one: but there does not appear sufficient reason, as Dr. Withering observes, for considering these varieties as really distinct; neither the height of the plant, the more or less ovate or lanceolate form of the leaves, nor yet the season of flowering or stations, affording any permanent distinctions.

Butterfly Orchis occurs in Norwood, Surrey; in Charlton-wood, and on Pens-common near Beckenham, Kent; Madingley-wood, Whitwell, Linton-wood, Balydon-hill, Kingston-wood, Gamlingay-wood, Cambridgeshire; Shotover-hill and Tar-wood, Oxfordshire; Short-wood near Pucklechurch, Gloucestershire; Envil in Staffordshire; woods and shady lanes in Leicestershire, common. It flowers in may and june.

17. Stem a foot and half high, leafy, round, upright, striated above the leaves. Lower leaves linear, sharpish, unspotted, the upper more inclined to lanceolate, springing from a sheath rendering the stem angular under the back of the leaf, four in number at most. Bractes lanceolate, acuminate, pale green, about the length of the flowers, the upper ones gradually shorter. The flowers have the same scent with O. odoratissima, only weaker. Germ twisted green. Corolla white.

Native of the mountains of Austria: flowering in august. The two outer petals, spread out like the wings of a bird in the act of flying: whence the name [a].

18. Root-leaves ovate. Scape a foot high. Leaves alternate, remote, sheathing, lanceolate, small. Flowers small, remote. Corolla resembling the papilionaceous, with the banner and wings whitish flesh-colour, wing-petals two, filiform, under the banner, and of the same length, keel or lip, very pale yellow with black dots, wider, imbricate-waved.—Native of the Cape of Good Hope [b].

19. Root-leaves two, ovate.—Native of Siberia [c].

20. Bulbs oblong, conical. Scape firm, a foot or eighteen inches high, leafy. Leaves lanceolate. Spike short, very much crowded. Bractes the length of the germ. Flowers frequently turned upside down, so that the lip turns to the base of the spike, and the helmet or hood recedes from it. The latter is formed of the three outer petals, bent round the stamineous column, ovate with an awn half the length of the petal, the end of which is wider and almost club-shaped. The two inner petals cover the stamineous scape, are wide, lanceolate, with a shorter awn. Lip short, three-parted, with the lateral segments quadrangular, the middle one wider, emarginate, with a spinule from the incision. The whole corolla bright purple with deeper spots on the lip. Spur a third part of the length of the germ [d].

According to Jacquin's description, it is from six inches to a foot in height, upright and elegant; leaves oblong; spike roundish; corolla purple flesh-colour, nectary dotted with red, horn blunt, half the length of the germ, lip trifid with blunt segments, the lateral ones quite entire, the middle segment trifid, the petals run out into a bristle widening at the top and blunt.

Villars observes, that the leaves are of an ash-coloured green, and more approximating to the stem than in the other sorts, spike very close and pyramidal, of a grayish red, each outer petal terminates in a thread in form of an antenna at the extremity, nectary short, the lower lip divided into three parts, the middle one wider and a little emarginate, flowers oblique not reversed.

Scopoli thus distinguishes it from *pyramidalis*, with which it has been confounded: spike blunt, oval, dense, and in a manner umbelled; leaves blunt, with the nerve ending in a point; petals tailed; breast of the beard neither eared nor spotted, with acuminate segments; spur not long. He says that it was first observed by Dalechampius.

Native of Germany, Austria, Carniola, Switzerland, the South of France and Italy.

[a] Jacquin. [b] Linn. amoen. [c] Linn. spec. [d] Haller.

21. Bulbs ovate. Stem from eight to fifteen inches high, round or slightly angular, smooth and firm, almost covered with leaves. Lower leaves sheathing the stem, lanceolate, very acute, pale green marked with numerous parallel veins and irregularly reticulated with cross ones; middle ones embracing the stem; upper sessile, closely converging, lanceolate but more obtuse than the lower, shining within and semitransparent, nearly covering the whole stem. Flowers numerous, (eighty) crowded in a short blunt cone, forming a most elegant termination to the stem, deep flesh-colour or pale purple. Bractes membranaceous, lanceolate, very acute, green with a tinge of purple, as long as the germ. Petals ovate-lanceolate, the middle of the exterior and the two interior converging, the exterior lateral ones spreading: hood of the nectarium very short, scarcely perceptible; cases of the anthers small. Stamens short, yellow; anthers green. Lip of the nectarium broad, with two oval gibbous prominencies at the top, and at bottom deeply divided into three nearly equal somewhat rounded lobes: spur awl-shaped, somewhat curved, longer than the germ: the spurs are all turned to the inside of the cone, so that the lips of the nectaria form a regularly imbricated outer surface to the cone [e].

Dr. Stokes remarks the silky glossiness of the leaves, which are linear-lanceolate: and Dr. Smith, that the bulging protuberances on the lip of the nectary give the distinguishing character of the species.

According to Linnæus, the stem is a palm high and jointed; leaves five or six, lanceolate, pointed, membranaceous; bractes lanceolate, coloured, as long as the germ; flowers purple, with ovate-lanceolate petals, three approaching, the two lateral ones spreading and bent back; lip two-horned, trifid, equal, quite entire; spur very long.

Scopoli says that the scape is a foot high, the helmet has spreading wings, the lateral segments of the beard crenulate, the spur scarcely longer than the germ, the pollen brownish, and that it differs from *conopsea*, in the roots, the shortness of the spike, and the pectoral auricles. These two longitudinal parallel concave rounded auricles on each side the base of the trifid lip are indeed the character that distinguish this species from all the rest, as observed above.

Ray remarks the same circumstance, as also that the corolla is sometimes white, which is the case with many other species that grow in a calcareous soil, as this does.

Mr. Woodward observes that Haller's figure being taken when the flowering was far advanced, the pyramidal form of the spike is lost; the figure in the third edition of Ray's synopsis represents it well.

Native of many parts of Europe, as Sweden, Belgium, Switzerland, Austria, Carniola, France, Italy, and Britain. With us about Harefield in Middlesex, Dartford in Kent, Stocking-wood in Leicestershire, Chesterton, Hinton, Devil's-ditch near Newmarket and Linton in Cambridgeshire, Whichwood-forest, between Woodstock and Enston, and on Caversham warren in Oxfordshire: also in Scotland. It flowers later than the other Orchises.

22. Bulbs orbicular, small, accompanied with strong fibres. Stem erect, a foot high, round, jointed, smooth, leafy. Leaves seven or eight, all sheathing, the lowest four inches long, the others gradually less, bright green, very smooth, five or six of them spreading, the others rolled round the scape. Spike close, from above an inch to two inches in length. Bractes lanceolate, the length of the germ. Helmet or hood three lines long, the five petals of which it is composed so closely joined as to seem three, acuminate, pale red; lower lip trifid, above two lines wide, reflex, the middle segment sharpish, quite entire, a line in width, the lateral ones crenulate, all green tinged with dusky purple; aperture white or reddish; horn blunt, the length of the germ [f]: or shorter, according to Linnæus.

The flowers smell like a goat according to some, and like a bug, according to others. Haller says, that

[e] Woodw. Mfs. [f] Pollich.

whilst

whilſt it is withering it ſtinks abominably. Native of Denmark, Germany, the ſouthern parts of Europe, and the Levant, in paſtures, flowering in june. Ray found it in flower on the 26th of may near Geneva, in the paſtures on the other ſide the Rhone.

This ſpecies is inſerted in Mr. Hudſon's catalogue, with a note that he never found it. Orchis barbata fœtida minor flore albo, *Jun.* 376. is not this ſpecies, but probably a variety only of Satyrium hircinum. Cluſius mentions, that he found an Orchis near London, with a ſpike of purple flowers which was extremely fetid, but Ray ſays he is ignorant what it could be, and that he never could find any thing of the ſort.

23. Root fleſhy, ſeeming to be obſcurely teſticulated, with capillary fibres at the baſe of the ſtem. Stem a foot and half high. Leaves towards the root four or five, alternate, ſheathing, lanceolate; the reſt of the ſtem without leaves, having about ten acuminate ſheathing bractes. Spike very narrow, naked, almoſt a ſpan long, with lanceolate bractes between the flowers, of the ſame length with them. Horn filiform, ſhorter than the germ. Upper lip equal, converging; lower three-parted, the middle ſegment ovate, the lateral ones filiform.—Native of the iſland of Ceylon[g].

24. Bulbs roundiſh, the ſize of hazel nut or of a nutmeg, one fixed to the baſe of the ſtem, and the other connected to the baſe by a fibre half an inch long, and the thickneſs of packthread, in the ſame manner as in O. bifolia; above them are lanugh ſpreading fibres. Stalk from ſix or ſeven inches to a foot or more in height, upright and leafy. Leaves embracing, lanceolate, marked with lines, glaucous, ſhining on the upper ſide, underneath ſilvery; the bottom ones for the moſt part turning back and variouſly contorted. Flowers few, from ſix to eight, ſeldom more than twelve, purple, ſitting looſely on the ſtalk. Bracte almoſt the length of the germ, purpliſh and incumbent. Petals cloſing ſo as to form a helmet or hood; the two outermoſt ſtrikingly marked with green parallel lines: lip broad, purple, whitiſh in the middle and dotted, having three lobes, of which the two ſide ones turn downward, the middle one is ſhorteſt with a notch in it; all are finely ſerrate: ſpur nearly the length of the germ, ſlightly notched at top, and tending upward. Anthers green, club-ſhaped, ſplitting into two lamellæ[h].

Mr. Woodward ſays the leaves are not ſpotted: according to Mr. Stackhouſe, they are ſometimes ſpotted in the ſpring, the ſpots growing paler as the flowers advance.

According to Mr. Woodward, it differs from the *maſcula* in being a lower plant, and the ſpike conſiſting of fewer flowers, the petals all blunt and converging, the three outer forming the hood and covering the lower ones, and always ſtriated with green veins, whatever may be the colour of the flower; the interior petals are alſo much ſmaller, the lip of the nectarium three-lobed nearly equal, the two outer lobes crenate, reflected and ſtriated with purple veins, the middle one notched and dotted upwards; horn broad and blunt, ſhorter than the germ. Anthers yellow. Flowers dark or pale purple, fleſh-coloured or white.

There is no ſpecies more variable in this reſpect, but in all the varieties it retains more or leſs ſtrongly, the green lines, which, as Ray obſerved long ſince, obviouſly diſtinguiſh this from all our other Orchides[i].

Retzius remarks, that it differs not only in the colour but the form of the flower; the lip of the nectary being inflex or flat, four-cleft, undivided, or ſlightly emarginate: the horn or ſpur alſo is blunt and gibbous, cylindric, compreſſed or ſubcompreſſed.

Mr. Curtis remarks that he has not heard of any one who has raiſed this or any other Orchis from ſeed, and that he cannot boaſt of having done it himſelf; yet that frequent obſervation almoſt confirms him in the opinion that they muſt be propagated from ſeed, for if this be not admitted, how ſhall we account for ſo many young plants being found together as are frequently obſerved? This entirely agrees with my own conjecture made above under *O. bifolia*, before I had ſeen what Mr. Curtis has advanced on the ſubject.

This has been ſaid to be the true ſort which produces the oriental Salep, but it is clear that more ſpecies than one are uſed for it, becauſe ſome of the roots imported in that drug are undivided, as in this, and others are palmated. Some of the other ſpecies have larger roots than this, and the quality of all appears to be the ſame.

O. morio grows in meadows that are moderately dry, ſuch as the Cowſlip is uſually found in, and ſometimes it is ſo abundant as to empurple the ſpot it grows on[k]. I have found great quantities of it on the balks and headlands of corn fields. It flowers in may and june.

25. Bulbs large, oval, both fixed to the baſe of the ſtem, which is about a foot high, round, ſmooth, upright, ſolid, above naked and purpliſh, below cloathed with ſurrounding leaves; theſe are lanceolate, alternate, broadiſh, the lower ones ſheathing at the baſe, ſpreading upwards, bright green and ſhining above, glaucous beneath, marked longitudinally with parallel veins, and uſually ſpotted with large brown or dark purple ſpots: the upper leaves cloſely ſheath the ſtem and are pale green. Flowers in a looſe ſpike, numerous. Bractes lanceolate, membranaceous, longer than the germ, (the length of the germ as Haller, ſhorter than the germ as Curtis and Relhan, of the ſame length or a little ſhorter, as Pollich affirms; according to Jacquin, the loweſt are twice the length of the germ, and the reſt are of an equal length with it,) pale purple, a little twiſted at the top. Flowers darker or paler purple, rarely white: covers of the ſtamens dark purple: petals lanceolate, acute, of the three upper the two outer are erect and reflected back to back, the middle one ſpreads and lies over the two lower ones, which are cloſely convergent, of a paler colour, and form an arched hood to the ſtamens: lip of the nectarium broad, dotted at the upper part, three-lobed, the outer ones roundiſh, crenate, the middle longer and notched at the end: horn as long as the germ, or longer, *Hall.* ſhorter, *Reik.* broadeſt and ſomewhat compreſſed at the point: mouth white. Anthers greeniſh, elaſtic like the reſt of the ſpecies[l]. As the plant advances towards maturity, the filaments in many of the Orchiſes hang out of their cafes towards the ſtigma, and when they are drawn out, at the baſe of each is a ſmall tranſparent globule, and at the top a club-ſhaped ſubſtance, moſt commonly yellow and granulated, which muſt be conſidered as the anther; in the microſcope it appears to be compoſed of cubic or irregularly quadrangular corpuſcles, united by fine elaſtic threads.

According to Linnæus, this is very cloſely united to *morio*, but the ſtem is as tall again; the flowers more numerous, the two petals on the back bent backwards, and not at all approaching to form a helmet or hood; the middle lobe of the lip is ſmalleſt.—Mr. Curtis remarks, that the ſpotted leaves and early bloom will in general be ſufficient to diſtinguiſh this ſpecies. If ſo, Pollich muſt have been miſtaken, for he ſays that it flowers in june, and that his ſpecimen had no ſpots on the leaves.

Haller obſerves, that the bulbs have a goatiſh ſmell and that it differs from *morio* in having the outer petals ſharper and longer, the cowl or hood looſe or wandering, the lip longer, with its middle ſegment produced farther beyond the lateral ones, without any green lines, the ſtem alſo is loftier, the leaves wider and ſpotted.

Retzius remarks, that this ſpecies is no leſs variable than the preceding; the lip of the nectary being entire, emarginate and more or leſs four-lobed; the horn conical or cylindrical.

The ſpikes of theſe flowers, ſays Lightfoot, are the *Long-Purples* or *dead men's fingers*, which helped to compoſe Ophelia's garland:

[g] Linn. mſſ. [h] Curtis. [i] Idem. [k] Curtis. [l] Woodw. Mſſ. and Curtis.

" There with fantastic garlands did she come,
" Of crow-flowers, nettles, daisies and *long purples*,
" That liberal shepherds give a grosser name,
" But our cold maid's do *dead men's fingers* call them."
Hamlet, Act 4.

The latter name would agree better with *O. latifolia* or *maculata* which have palmated or handed roots, divided and spreading out like the fingers, whereas this species has two solid roundish bulbs. I do not find the name of *Long Purples* in any of our old English herbals.

It is native of most parts of Europe, and is common in most parts of England in woods and meadows, flowering in april and may.

The roots abound with a glutinous slime, of a sweetish taste, and a faint somewhat unpleasant smell. This mucilaginous or gelatinous quality of the Orchis root has recommended it as a demulcent, and it is generally used in the same complaints as the roots of Althæa, and gum arabic.

Salep, which is imported from the East, and was formerly held in great estimation, is now well known to be a preparation of Orchis roots, as was first suggested by Mr. Joseph Millar, in his Botanicon officinale, 1722. This is the species commonly regarded as the officinal one, and it has place in the Materia Medica of the Edinburgh Pharmacopœia; other species however are employed in making Salep, and it should seem that they have all the same quality.

Mr. Mault of Rochdale has given the method of curing the Orchis root as follows: the new root is to be washed in water, and the fine brown skin which covers it is to be separated by means of a small brush, or by dipping the root in hot water, and rubbing it with a coarse linnen cloth. When a sufficient number of roots have been thus cleaned, they are to be spread on a tin plate, and placed in an oven heated to the usual degree, where they are to remain six or ten minutes, in which time they will have lost their milky whiteness, and acquired a transparency like horn, without any diminution of bulk. Being arrived at this state, they are to be removed, in order to dry and harden in the air, which will require several days; or by using a very gentle heat they may be finished in a few hours. The properest time for gathering the roots is when the seed is formed, and the stalk is ready to fall, because the new bulb is then arrived at its full maturity, and may be distinguished from the old one by a white bud rising from the top of it, which is the germ of the stem for the succeeding year[a].

Salep, considered as an article of diet, is accounted extremely nutritious, as containing a great quantity of farinaceous matter in a small bulk, and hence it has been thought fit to constitute a part of the provisions of every ship's company to prevent a famine at sea. For it is observed by Dr. Percival, that this powder, and the dried gelatinous part of flesh, or portable soup, dissolved in boiling water, form a rich thick jelly, capable of supporting life for a considerable length of time. An ounce of each of these articles, with two quarts of boiling water will be sufficient subsistence for one man a day. Dr. Percival not only recommends the use of Salep in diarrhœa, dysentery, dysury, and calculous complaints, but he thinks that in the symptomatic fever, which arises from the absorption of pus, from ulcers in the lungs, from wounds, or from amputation, Salep used plentifully is an admirable demulcent, and well adapted to resist that dissolution of the crasis of the blood which is so evident in these cases. The supposed aphrodisiac qualities of this root, which have been noticed ever since the time of Dioscorides, seem to be founded on the fanciful doctrine of signatures[b].

It is to be hoped, says Dr. Withering, that we shall no longer be supplied from foreign markets, with an article that our own country can supply us with in almost any quantity.

26. Bulbs oval. Stem from four to six or eight inches high, angular, almost hid by the upper leaves. Leaves four, five or six, bluntly lanceolate (more or less acute, *With.*) bright green above, whitish green beneath, shining, marked with numerous longitudinal veins or nerves. Flowers numerous (near forty) in a close short ovate spike. Bractes about two thirds of the length of the germ, membranaceous, faint purple with a dark keel, (rather shorter than the germ, *With.*—as long as the germ, *Relh.*). Petals all convergent, the three outer oval-lanceolate, acuminate, purple without, greenish white within; the two inner lanceolate, narrow; lip of the nectarium white with purple spots, very deeply divided into three lobes, the two outer patent, lanceolate, entire, or with one or two teeth, middle one longer, widening at the end, and divided again into two short lobes, with an intermediate point: horn very short, blunt and slightly curved, half as long as the germ: cafes of the anthers greenish white, close. Stamens very short. Anthers pale yellow[c].

Dr. Withering remarks that the middle segment of the lower lip of the nectarium has not always the intermediate or projecting point, and that he has not found the roughness on it, mentioned by Linnæus in the specific character.

The characters of the species, according to Scopoli are, that the flowers are small, becoming gradually so pale, that the lip and spur at length turn white; that the bractle is almost equal to the lip; that the stamineous machine is blunt, with white cells, and yellow stamens; and that the beard or lower lip is variegated with blood-red spots, one of which, next the throat, is larger than the rest.

Villars remarks, that this is one of the smallest species, the leaves narrow, glaucous or silvery, spike short, ovate, close, small, appearing blackish at the top, whence its name of *ustulata*, and bright red or whitish towards the base; this appearance is caused by the upper petals, which open last, being of a very deep colour on the outside, and of a bright red within, contrary to the usual case with flowers, which have commonly the colours lighter in the parts most exposed to the air: the spur or horn of the nectary is short that it might be taken at first sight for a *Serapias*: the lower lip has five lobes rather than three or four, for the middle division subdivides into two shorter, which have a little blunt very short appendix at their point of separation: the two lateral ones are shorter and oblong: both are whitish, marked with salient cogged spots of a very bright and pleasant red: petals open, lanceolate, whitish within, and of a very deep almost black red on the outside.

This elegant little plant is distinguished at first sight by its small dotted flowers. It is in great quantity on many of our downs, and affects a dry calcareous soil. About Harefield in Middlesex; on Gogmagog-hills, Devil's-ditch, Chippenham, Cambridgeshire; Barneck-heath, near Stamford, and between Stamford and Duddington in Northamptonshire; on Wick-cliffe, and on the Wiltshire downs, as on Salisbury-plain, particularly on the barrows near Stonehenge; on Burford-down and Caversham-warren in Oxfordshire. In flowers in may and june.

27. Bulbs somewhat oval. Stem about one foot high, round and smooth. Leaves about four, sheathing, acutely lanceolate, the three lower spreading, the upper one closely embracing, bright green with numerous parallel veins. Spike from one to two inches long, with numerous flowers. Bractes very short, membranaceous, oval but pointed, and terminated with an awn. Petals all convergent, three exterior large and broad, oval-lanceolate, acute, two interior narrow, linear or somewhat awl-shaped, all greenish white with purple lines: lip of the nectarium purplish, or white with purple dots, long and narrow, divided into three segments, the two outer near the upper part, linear, half as long as the lip, the lower again slightly divided into three, the two outer broader, rounded, slightly serrate, the middle one appearing like a spine: horn blunt, half as long as the germ: cafes to the anthers distant: anthers yellow[d].

[d] Idem.

Meadows

Meadows and paſtures in a calcareous ſoil. Cawſham hills by the Thames ſide, not far from Reading, Berkſhire, and near the old chalk-pit by the paper-mill at Harefield; Caverſham-warren in Oxfordſhire.

β. Bulbs oblong, large. Lower leaves ovate-oblong, a little blunt, from two to three inches broad, gloſſy, ſcored, in ſome ſpecimens tranſverſely wrinkled, of a lively green colour; the uppermoſt narrower and ſurrounding the ſtalk. Stalk a foot, two feet, and ſometimes more in height, round, ſmooth, green below, purple above. Flowers numerous, cloſely imbricate, in a long ovate-cylindrical ſpike. Bractes very ſhort, ſcarcely the length of the ſpur of the nectary, ovate-acuminate. Petals cloſing and forming a helmet: the three outermoſt ovate, pointed, faintly three-ribbed, concave, marked with ſpots of a brownith purple colour running together, the two innermoſt much narrower, oblong, a little dilated towards the top, paler, marked alſo with purple ſpots. Spur of the nectary ſomewhat flattened, ſlightly bifid, ſcarcely reaching to the middle of the germ: lip large, broad, rough, with prominent purple dots, which as Haller juſtly obſerves, are little tufts of ſhort hairs, in flowers lately opened of a deeper purple colour, eſpecially on the edges, divided into four ſegments, the two uppermoſt of which are nearly linear and diverging, the two lowermoſt thrice as broad, diverging, the tips ſomewhat truncated, irregularly and finely notched, with a ſhort point for the moſt part between the two. Cafes of the ſtamens purple. Filaments yellowiſh. Anthers ſomewhat club-ſhaped, whitiſh. Germ roundiſh, twiſted, ſmooth, variegated with green and brown[1].

According to Dr. Withering the ſtem is from eight to twelve inches high; the ſpike about three inches long; the leaves ovate-lanceolate; the corolla varying much in colour, of a pale roſe red, with ſometimes a grayiſh caſt on the lip, and of a deeper purpliſh hue on the upper petals.

Mr. Curtis who, with Ray, Haller, Jacquin, Vaillant and others, makes this a diſtinct ſpecies, obſerves, that in expoſed aſpects its uſual height is about nine inches; in woods and coppices where it is more ſheltered, and where the ſoil is richer, it will acquire the height of two feet or more: ſuch ſpecimens ſurpaſs every Britiſh Orchis; its flowers vary exceedingly in colour, ſome being of a light, others of a deep purple colour; now and then one wholly white occurs: the lip of the nectary varies alſo in breadth. Both root and flowers ſend forth a ſtrong ſmell, ſomewhat like, but not ſo pleaſant as Anthoxanthum. Dr. Smith remarks that all the varieties ſmell like new hay.

Orchis fuſca is found on chalky banks, abounding in Milkwort and Juniper, near woods, and in the woods themſelves, in many parts of Kent, eſpecially about Rocheſter, near Northfleet, &c. It flowers early in May, and in forward ſeaſons at the cloſe of april, with early ſpotted Orchis, Cowſlip and Harebell[2].

It does not appear to Dr. Withering that theſe can well be made diſtinct ſpecies. The colours are conſeſſedly variable, and the lower lip may be deſcribed as three-cleft, conſidering the middle ſegment as notched, with a projecting point in the notch; or as five-cleft, when this little projecting point muſt be reckoned as one of the ſegments: the upper petals are confluent, and the lip dotted: the greater or leſs breadth of the middle ſegment of the nectary is the principal difference.

28. This has the ſtature of O. militaris, and almoſt the ſame flower; but the lip is very large, the full ſize of the thumb nail, wider than its length, retuſe or emarginate, undivided, toothleted, purple as the flower is[3].

Scopoli ſays, that the ſcape is ſcarcely half a foot in height; ſpike few-flowered (two or three) red. Flowers marked with lines: petals converging: lip ovate, toothletted, blunt: ſpur converging, acute, ſhorter than the germ and lip. Bracte wide, red, longer than the germ and lip.

Native of Spain and Carniola.

β. O. rubra. This beautiful plant is a variety of Linneus's papilionacea, with a ſmaller lip. Jacquin deſcribed his *rubra* from a bad drawing ſent him from Rome, with the petals too much expanded. Dr. Smith, who makes this obſervation, found it flowering on the ſecond of april, in the garden of the Villa Borgheſe near Rome.

29. Stature of *moria*, appearance of *ſambucina*, but the bulbs not palmate. Flowers yellow: lip deeper yellow, unſpotted, trifid, quite entire, middle ſhorter, emarginate: horn of a middling length, ſubemarginate, aſcending[4].

Hallen obſerves that it agrees in many circumſtances with *incarnata*, which he makes the ſame with *ſambucina*; that the root-leaves are two inches wide; the ſtem naked, and ſcarcely a long ſpan in height; the ſpike is thin and few-flowered; bractes yellowiſh, ſhorter than the germ. Petals turned up and bent back: uppermoſt ovate, marked with three lines bending itſelf over the ſtaminoeous cape; the two lateral ones ſtraightiſh, ovate-lanceolate, blunt, divided by three lines, pale yellow; inner petals yellow, wider and blunter than in *moria*, divided by one green line; lip yellow, trifid, convex, villoſe at the opening, the lateral ſegments ſmaller than in *moria*, the middle one ſhorter, wider, emarginate, but not toothed, as in *moria*; ſpur more ſlender, almoſt the length of the germ, bowed back upwards at the end: it has no ſpots.—The leaves are wider than in *moria*, the lines of the petals fewer, the fourth and fifth petal wider, with a longer ſpur, curved up, and the lip not ſerrate. It ſmells like the urine of cats. Villars found it to be perfectly like that of the freſh flowers of Elder, inſomuch that he took it for the *ſambucina*, till he inſpected the roots.—He remarks that the bulbs are round and unequal, the leaves tender wide upright and pointed, the ſtem ſix or eight inches high, ſpike yellow oblong irregular, with the flowers inſulated, nectary ſlender, cylindrical, the length of the germ, lower lip divided into three equal lobes, the extremity of which is ſuddenly rounded; upper petals open and reflected. This ſort is nearly allied to O. maſcula, but the flowers are more inſulated, more rounded at the end, and have an ill ſmell, which that has not.

Native of Switzerland, Auſtria, Dauphiné, Italy.

30. The whole plant is hiſpid, the ſize of O. Monorchis. Root-leaves two, kidney-form, embracing. Scape half a foot high. Spike directed one way, with minute flowers. The three outer petals calyx-formed, ovate, villoſe: the two inner linear, ſmooth, double the length of the others: lip of the nectary divided into five linear ſegments: horn curved in, the length of the flower.

Native of the Cape of Good Hope, where it was found by Sparrmann.

31. Raceme large, many-flowered. Flowers large, pure white. Found at the Cape by Thunberg.

32. Bulb generally ſingle, ovate, villoſe, the ſize of a pigeon's egg; a few fungoſe villoſe fibres iſſue from the baſe of the ſcape, near its inſertion into the top of the bulb. Leaves from four to eight, radical, preſſing on the ground, ſmooth, deep ſhining green, ſomewhat fleſhy, many-nerved, about four inches long, and three broad. Scape erect, about a foot and half high, including the flower-bearing part, about as thick as a gooſe quill, round, ſmooth, at every inch and half or two inches having a lanceolate leafy ſheath. Spike four to ſix inches long, every where ſurrounded with flowers, which are ſolitary, white and fragrant. Bractes lanceolate, nerved, as long as the germ. The three exterior petals nearly equal; two interior ſmall, obliquely oblong, erect. Upper lip of the nectary ſhort, under-three-parted: middle diviſion long, narrow, pointed, recurvate. Horn nearly twice the length of the germ, perpendicular, or nearly ſo.

Native of Coromandel, in moiſt valleys among the hills; flowering in the rainy ſeaſon[5].

Species with divided or palmated bulbs.

33. Bulbs broad and flat, divided into a few fingers, which ſometimes run out into a long fibre, ſtanding

[1] Curtis. [2] Linn. ſpec. [3] Linn. mant. [4] Roxburgh.

downwards; ſeveral ſhort thick fibres alſo ſhoot out laterally from the top of the bulbs. Stem about a foot (or eighteen inches) high, ſmooth, hollow, ſomewhat angular towards the top. Leaves five or ſix, alternate, ſheathing the ſtem to the ſpike, acutely lanceolate, keeled and marked with parallel veins, pale green, rarely ſpotted, and when ſo, very obſcurely. Bractes much longer than the flowers, reſembling the uppermoſt leaves, acutely lanceolate, green, ſometimes with a tinge of purple. Flowers very numerous (forty), in a cloſe ſomewhat conical ſpike, for the moſt part roſe or fleſh-coloured with us, often purple, rarely white. Petals lanceolate, the two outer of the upper ones reflex; the middle one and the two inner converging; lower lip of the nectarium obſcurely three-lobed, ſerrate, middle lobe longeſt, narrow and ſomewhat pointed, marked with dots and lines, forming a regular figure, following the form of the lower lip. Spur ſhorter than the germ, regularly conical*, blunt, incurved. Anthers roundiſh, club-ſhaped, yellowiſh green*. Germ twiſted.

There are ſome variations in the ſegments of the lip of the nectary, as obſerved by Retzius in *morio* and *maſcula*; whence Dr. Stokes has noticed three varieties of this Orchis*.

Linnæus diſtinguiſhes this ſpecies from *maculata*, by its bractes longer than the flower, the want of ſpots on the leaves, and its hollow ſtem.—With us the leaves are ſeldom ſpotted; or if at all, obſcurely; Villars ſays that they are frequently ſpotted in Dauphiné, but leſs than in *maculata*. According to him, the ſpur is longer than the germ, if it be obſerved during the time of flowering; for after that time the germ lengthens, and the nectary is then the ſhorteſt. This obſervation of Monſ. Villars is well founded, and has not been ſufficiently attended to.—He deſcribes the lower lip as almoſt entire, wider than its length, divided into three lobes, of which the middle is the ſmalleſt, often toothed, of the ſame length with the lateral lobes, which are turned back.—He remarks that the old authors have abundance of figures and ſynonyms of this Orchis; that Haller has collected a hundred of them, which is not half the number.

Haller compares this ſpecies with *maculata* which it moſt reſembles, but the leaves are wider; the ſtem ſoft, hollow, and lower, the bractes longer than the flowers, and giving the ſpike a peculiar and leafy appearance, flowers larger, the ſpots and lines on the lip not ſo regular.

Native of Europe in wet meadows and marſhes, commonly with Valeriana dioica, Menyanthes trifoliata, and Lychnis Flos Cuculi: flowering towards the end of May. Loureiro found it alſo in Cochinchina.

34. This very much reſembles the preceding; but the leaves are pale green and unſpotted, not dark green and ſpotted; the ſtem is ſhorter by half; the bractes are ſcarcely longer than the flower or germ; the corolla is pale fleſh-coloured, not red; the two dorſal petals are quite bent back, not merely ſpreading, nor are they ſpotted*. Our *latifolia* has pale green leaves, rarely ſpotted, and the corolla is frequently pale fleſh-colour. The *incarnata* however is probably no more than a variety of the *ſambucina*, as Haller, Scopoli and Villars have inſiſted.

35. This is eaſily diſtinguiſhed from *O. latifolia* by its having few flowers, the ſtem leafy only below the middle, the bractes by no means longer than the flowers, the leaves not at all ovate-lanceolate, but almoſt tongue-ſhaped, as in *O. maculata*, from which it is alſo very diſtinct in the fewneſs of its flowers, the want of notches in the lip, the greater length of the horn, the having no ſpots on the leaves, the roots leſs divaricated, and the whole habit. It is different from all the ſpecies in the ſtructure of its fructification, the yellow colour of the flowers varying to purple, its ſtation in wet places on mountains, and in flowering very early with Corona Imperialis*.

Scopoli cannot diſcover any mark in the long deſcription given by Linnæus in the Flora ſuecica of the *ſambucina*, by which it can be diſtinguiſhed from his *latifolia*. We may conclude therefore that his *latifolia* is the ſame with the *ſambucina* of Linnæus, and probably his *conopſea* is our *latifolia*.

Villars ſays that this ſpecies differs from *latifolia*. 1. In having the bractes ſhorter than the flowers. 2. The lower lip almoſt flat or very little convex, whereas the lateral lobes are turned back in the other. 3. The nectary blunter and ſhorter. 4. The lateral petals raiſed very much as if they were broken, inſtead of being carried forwards and a little open.

The ſtem is about half a foot high, thick and ſolid; the flowers red and purple in the *incarnata*, yellowiſh-white in this.

Native of ſeveral parts of Europe, but not of Britain. It has the ſmell of Elder flowers, whence the name.

36. Bulbs palmated, compreſſed, with the ſegments much divaricated. One of them, according to Linnæus, floats in water, and nouriſhes the ſtem, the other ſinks and bears the bud for the next year. But with us it does not grow in water, only ſometimes in moiſt meadows. Stem ſolid, from ſeven or eight to eighteen inches high, the lower part round, the upper ſomewhat angular. Lower leaves embracing the ſtem, loweſt conſtantly ſhort, broad and blunt, the next conſiderably longer, bluntly lanceolate, above theſe more acutely lanceolate, upper ones very narrow and apparently ſeſſile, but the margins are decurrent, whence the angular appearance of the ſtem; beneath they are ſilvery green, with parallel green nerves, above pale green, often partially covered with the ſame ſilvery ſkin, marked with numerous reddiſh brown ſpots, moſtly oval and tranſverſe, but ſometimes irregular. Flowers numerous (forty) in a cloſe conical ſpike. Bractes acutely lanceolate, much longer than the germ, (or, according to Dr. Stokes, the lower longer, the upper ſhorter than the flowers;) purpliſh, if the upper part of the ſtem be ſo, but green, if this be green. Corolla uſually pale purple: petals acutely lanceolate, the three outer patent, ſometimes ſpotted, the two inner converging: lip of the nectarium deeply trifid, outer ſegments angular and notched, middle one longeſt narrow and lanceolate, all marked with purple ſpots and lines: horn rather blunt, ſhorter than the germ: (or of the ſame length, *Relh.*) cafes of the ſtamens dark purple, ſtanding cloſe: ſtamens very ſhort: anthers green.—This is readily diſtinguiſhed from the *latifolia* by the ſolid ſtem, the lower leaf always very blunt, the ſpike conical, which in the other is ſomewhat cylindrical, and in flowering later*.

It varies with white flowers, and the leaves are ſometimes not ſpotted*.—Orchis maſcula and morio, and ſometimes latifolia having ſpotted leaves, confuſion has hence ariſen, by giving too much attention to the trivial name of this ſpecies*.

Native of moſt parts of Europe in moiſt meadows and woods; ſometimes in barren paſtures, when the ſpike is only half the ſize, and has fewer flowers*. It flowers in June and July.

37. This is not a variety of O. conopſea, though they agree in many circumſtances. The ſtem is harder, the leaves are hard and ſtiff, pointing upwards, linear, four or five inches in length. Stem from a foot to eighteen inches in height. Bractes longer than the germ, with a long awn. Flowers pale or bright purple: the three outer petals ſpreading, the middle one almoſt ſtraight, ovate, ſomewhat ſerrate, the ſide ones tranſverſe, ſomewhat lanceolate: the two inner petals ſhort, lanceolate, ſlightly ſerrate, bent about the ſtamineous column, which they cover: lip ſmall, ſhorter than the uppermoſt petal, almoſt equally and not deeply trifid, the middle ſegment wider, moderately acuminate, the lateral ones a little narrower: ſpur ſhorter than the germ, widiſh, mucronate: ſtamineous column ſhort: anthers yellow. It has a ſingular, pleaſant, ſtrong ſmell.—The ſpur is only half the length of that in *O. conopſea*, but wider,

* Woodw. Mſ. * Curtis. * Wither. arr.
* Linn. ſuec. * Idem. * Woodw. Mſ. * Lightfoot. * Withering.
* Ray.

the

the petals ſerrate, the lip longer but not ſo wide, the middle ſegment more produced, and it is of a firmer habit[a].

The palmate bulbs are elongated in an irregular manner, the leaves are narrow, the ſpike of flowers is oblong, pale red mixed with white, the nectary of the ſame length with the germ, the lower lip three-lobed, the two ſide ones truncated, nearly equal, and as long as the middle one[b].

Native of France, Germany, Switzerland, Auſtria, Italy; Sweden alſo and Norway but rare.

38. Bulbs palmated, compreſſed. Stem twelve to eighteen inches high, ſmooth and firm, round below, angular upwards; lower leaves ſheathing the ſtem, long, narrow, and acutely lanceolate, bright green, ſhining, keeled, with a ſtrong midrib, on each ſide of which are two or three faint veins and one ſtrongly marked. Lower ſtem-leaves embracing, upper ſeſſile, lanceolate, acute, decreaſing in ſize till they reſemble the bractæ. Flowers fleſh-coloured or pale purple, (forty-two) in a looſe ſpike, three inches long. Bractæ lanceolate, acuminate, longer than the germ, herbaceous; the middle of the exterior, and the two interior petals oval-lanceolate, cloſely converging, their tips inflected and covering the ſtamens; the two exterior lanceolate, patent at right angles to the tip of the nectarium, which is ſhort and broad, and divided into three roundiſh ſegments, the middle one rather broadeſt and longeſt. Spur awl-ſhaped, curved, full of juice, ſemitranſparent, much longer than the germ. Stamens ſhort, with two gibbous fleſhy prominencies at their baſe: anthers greeniſh: opening of the ſtigma very apparent. Flowers ſmelling very ſweet[c].

It has ſome reſemblance to O. pyramidalis, from which it is diſtinguiſhed by the root, the narrowneſs of the leaves, and the length of the ſpike, as it is ſufficiently from every ſpecies of this diviſion by the great length of the horn of the nectary. The flowers are ſometimes white.

Native of many parts of Europe in meadows and paſtures; flowering in june. Hareſield in Middleſex, Aſply in Nottinghamſhire, King's hedges, Cheſterton, Hinton, Triplow, Devil's ditch, Cambridgeſhire, rough paſtures adjoining Cowley common in Oxfordſhire, on the Wiltſhire downs, paſtures under Shortwood near Pucklechurch, Gloceſterſhire, Knutsford moor, Cheſhire, in a moraſs near Leeds, near Auchin Dewney ſeven miles from Edinburgh, and abundantly on the hilly grounds north of the river Leven, Dunbartonſhire. In the moiſt heathy ground of Newton park, Ireland.

39. Lower leaves palmary, lanceolate, large. Spike narrow. Flowers obſoletely yellow. Native of Virginia[a].

40. Native of Siberia.

41. Stem a ſpan high. Leaves lanceolate-linear, alternate, the lower ones longer. Spike leafy. Upper lip trifid; lower obcordate, two-lobed. Horn of ſpur ſlender. Native of the iſland of Ceylon[b].

42. Stem a palm high with the Spike. Leaves alternate, lanceolate, the length of the ſtem. Spike ovate, with linear-lanceolate bractes, the length of the flowers. Corollas yelloviſh-green: uppermoſt petal wider, ovate; the two upper lateral ones lanceolate, converging to the firſt; the two lower lateral ones oblong: lip ſcarcely longer than the petal. Native of Iſland: found by Koenig[a].

43. Roots compoſed of thick horizontal fibres wrinkled tranſverſely. Stem ſtraight, upright, eighteen inches or more in height, blue or violet, leafleis but ſheathed with ſcales. Flowers in a very long thin ſpike, violet. Bractes the length of the germ. Spur conical, ſlightly curved, acutely pointed, longer than the germ: the lower lip oval and entire, which diſtinguiſhes this plant clearly from O. nidus avis, that has this lip prolonged and cloven, with the ſegments at right angles. Fruit the largeſt of any in the Orchis tribe[b].

[a] Haller. [b] Villars. [c] Woodw. Mſs.
[a] Linn. ſpec. [b] Linn. ſuppl. [a] Linn. mant.
[b] Linn. Villars, Woodw. Mſs. Haller.

Native of France, Germany, Switzerland, Auſtria, Norway. Mr. John Goodyer is ſuppoſed to have found this in the border of a field called Marborne, near Habridge in Haliborn, a mile from Alton in Hampſhire; the 29th of june 1624. He deſcribes the ſtalk as nine inches high, with a few ſmall ſharp-pointed ſhort ſkinny leaves ſet without order, very little or nothing at all wrapping the ſtalk, having a ſpike of flowers like thoſe of Orobanche, without tails or leaves growing amongſt them. The lower part of the ſtalk within the ground is not round like Orobanche, but ſlender or long, and of a yelloviſh white colour, with many ſmall brittle roots growing underneath confuſedly, folded together like thoſe of the common Nidus avis. The whole plant as it appears above ground, is of a violet or deep purple colour[a]. It has not been ſince found by any perſon, ſo that it is yet a doubtful native of Britain.

44. Stem upright, ſmooth, from ancipital acutely four-cornered. Leaves on the ſtem from three to five, alternate, ſeſſile, acute, ſmooth, quite entire, nerved, keeled, ſheathing at the baſe, two inches long. Spike ovate-oblong, many-flowered. Flowers blue-purple. Bractes lanceolate, nerved, a little longer than the germs. Petals flat, equal in length, three lines long; the uppermoſt or dorſal petal ovate, obtuſe, erect; the two outer lateral ones ovate, acute, ſpreading very much; the two inner lateral ones oblong, obtuſe, next the dorſal petal erect, below the middle dilated, and there toothletted, attenuated at the baſe: lip of the nectary a little longer than the petals, the diviſions wide, wedge-form, equal, flat, ſubdivided in the middle into awl-ſhaped ciliæ; the ſide ones divaricated, the middle one ſpreading. Germ half an inch long.

Native of Canada and Newfoundland. Introduced in 1777, by William Pitcairn, M. D. It flowers in july[a].

45. This has the habit of Orchis maculata. Stem with linear, acuminate, ſcattered leaves on it. Spike long, cloſe. Petals converging; the three outer ovate, the two inner oblong, ſubciliate. Lip reflex, the ſegments very narrow at the baſe, wedge-form, ciliate at the tip. Native of North America[a].

46. Root-leaves two, oval, petioled, blunt, almoſt the length of the plant. Spike of five or ſix flowers. Bractes lanceolate-oval, the length of the germ. The two outer petals of the flowers ſpreading a little, green; three converging and more tender: lip oval, emarginate, with the tips divaricating. Native of Virginia[a].

47. Stem half a foot high and more, ſomewhat flexuoſe. Root-leaves very many, linear, acute, ſhort: ſtem-leaves lanceolate, acuminate. Spike of eight or nine flowers, remote; germs clothed with bractes: uppermoſt petal pedicelled, arched, oval-oblong; the lateral ones ſeſſile, riſing up: nectary within the flower erect, turbinate, cowled; upper lip bifid, obtuſe, lower the ſame; horn capillary, hanging down, the length of the petals.

Native of the Cape of Good Hope, where it was found by Thunberg[a].

48. Root-leaves lanceolate-ovate, petioled. Scape leafleſs, except that there is a ſmall lanceolate leaf in the middle. Flowers alternate in an oblong ſpike: upper lip three-leaved, ovate; the middle leaf longeſt, lower lip a little longer, three-parted, almoſt equal, with linear ſegments: horn ſix times as long as the petals. Native of Kamtſchatka[a].

49. Stem ſomewhat angular, ſmooth, a ſpan high. Leaves alternate, half embracing, lanceolate, ſomewhat keeled, entire, ſmooth, longer than the internodes, about ſix, a finger's length; the upper ones narrower and ſhorter. Flowers in ſpikes, ſnow white, very many. Bractes lanceolate, the length of the flower. Perianth three-leaved: upper dorſal leaf ovate, concave, erect, entire, two lines long; the two lower lateral, ſubtriangular, concave, hanging down, the ſize of the upper one. Corolla three-

[a] Ger. emac. [b] Hort. kew. [c] Linn. ſpec.

petalled:

petalled: the two upper petals lateral, lanceolate, erect, forming a helmet, the length of the calyx; the lower two-horned; upper horn or lip cylindrical, a little attenuated, hanging down; the lower cylindrical, gradually attenuated, hanging down, recurved, three times as long as the capsule. Anthers ſeſſile, ovate, white, inſerted into the ſtigma. Pollen pedunciled, granulated, yellow. Stigma concave. Native of Japan, near Miaco; flowering in June.

50. Root-leaves ſeveral, equitant, enſiform, convoluted, revolute-ſickled, ſmooth, a finger's length, the lower ones ſhorter. Scape erect, ſmooth, ſhorter than the leaves. Flowers in ſpikes. Horn of the nectary curved, an inch long.

Native of Japan, near Nagaſaki, in the mountains, among ſhrubs.]

PROPAGATION AND CULTURE.

All the ſorts of Orchis for the ſingularity and beauty of their flowers, deſerve a place in every good garden; and the reaſon for their not being cultivated in gardens, proceeds from their difficulty to be tranſplanted; though this, I believe, may be eaſily overcome, where a perſon has an opportunity of marking their roots in their time of flowering, and letting them remain until their leaves are decayed, when they may be tranſplanted with ſafety; for it is the ſame with moſt ſorts of bulbous or fleſhy-rooted plants, which, if tranſplanted before their leaves decay, ſeldom live, notwithſtanding you preſerve a large ball of earth about them; for the extreme parts of their fibres extend to a great depth in the ground, from whence they receive their nouriſhment; which, if broken or damaged by taking up their roots, ſeldom thrive after; for though they may ſometimes remain alive a year or two, yet they grow weaker until they quite decay; which is alſo the caſe with Tulips, Fritillarias, and other bulbous roots, when removed, after they have made ſhoots; ſo that whoever would cultivate them, ſhould ſearch them out in their ſeaſon of flowering, and mark them; and when their leaves are decayed, or juſt as they are going off, the roots ſhould be taken up, and planted in a ſoil or ſituation as nearly reſembling that wherein they naturally grow, as poſſible, otherwiſe they will not thrive, ſo that they cannot be placed all in the ſame bed; for ſome are only found upon chalky hills, others in moiſt meadows, and ſome in ſhady woods, or under trees; but if their ſoil and ſituation be adapted to their various ſorts, they will thrive and continue ſeveral years, and, during their ſeaſon of flowering, will afford as great varieties as any flowers which are at preſent cultivated.

[Theſe plants, ſays Mr. Curtis, multiply themſelves very little, the ſmall increaſe they make appearing to be from off-ſets, that hitherto we have no ſatisfactory proof of their being propagated from ſeed; yet the ſeed-veſſels in many of them are large, well-formed, and filled with ſeeds, which though extremely minute appear perfect. The ſmallneſs of the ſeed is certainly no argument againſt its vegetating; ſome of the Ferns whoſe ſeeds are much ſmaller are now well known to be propagated from ſeed; and it is moſt probably owing to a want of minute attention, that the progreſs of Orchis ſeedlings has not yet been obſerved. Such as are diſpoſed to doubt the vegetative power of theſe ſeeds may perhaps urge that their barrenneſs is owing to their not being properly impregnated, the anthers in this tribe appearing to be different in their ſtructure from thoſe of other plants, and not containing, ſo far as we have yet been able to diſcover, any ſimilar pollen.

Mr. Salisbury of Chapel Allerton near Leeds in Yorkſhire, a very eminent botaniſt and ſkilful cultivator of rare exotic plants, has raiſed abundance of young plants from the ſeeds of the ſplendid Limodorum Taukervilliæ, ſo long ſince as the year 1785 or 1786. This is perhaps the firſt inſtance of the kind among the Orchis tribe[s], and may encourage ſkilful cultivators to try the experiment on ſome of the other genera.]

Leaves oval ſtand, ſpikes roundiſh compact puberſcent.

DESCRIPTION, *&c.*

1. This is a perennial plant with a low ſhrubby ſtalk, ſeldom riſing more than a foot and half high, dividing into branches. Leaves roundiſh, thick, woolly, hollowed like a ladle; they are like thoſe of common Marjoram, but of a thicker ſubſtance, and have much the ſame ſcent. The flowers are produced in roundiſh ſpikes, cloſely joined together at the top of the ſtalks; and at the end of the ſmall ſide branches, they are of a pale aſh colour, peeping out of their ſcaly coverings.

[Haſſelquiſt remarks that it is cultivated in the gardens at Cairo on account of its ſmell, which is ſtronger than that of Dittany of Crete, aromatic, and comforting the head; and that the Arabians call it Zatarhendi, that is Origanum indicum.

Native of Egypt. Cultivated in 1731, by Mr. Miller. It flowers from june to auguſt[1].]

2. This alſo is a perennial plant. Stalks hairy, about nine inches high, of a purpliſh colour, ſending out ſmall branches from the ſides by pairs. Leaves round, thick, woolly, very white. The whole plant has a piercing aromatic ſcent, and biting taſte. The flowers are collected in looſe leafy heads of a purple colour, and nodding; they are ſmall, and the ſtamens ſtand out beyond the corolla.

[The fabulous qualities attributed to Dictamnus may be ſeen in Virgil's 12th Æneid, and in Cicero de Natura Deorum, 2. 50.

Native of the iſland of Candia[2] and, according to Loureiro, of China near Canton. It flowers from june to auguſt. Cultivated in 1568, by Mr. Riche, as appears from Turner's herbal[3].]

3. This has a perennial root, but an annual ſtalk. The root is compoſed of many ſlender woody fibres. The leaves are oval, ſmooth, and of a grayiſh colour; the ſtalks are ſlender, of a purpliſh colour, ſmooth, near two feet high, ſending out ſlender branches oppoſite, terminated by ſlender oblong ſpikes of ſmall purpliſh flowers, peeping out of their ſcaly covers. The ſtamens are extended beyond the corolla to a conſiderable length. The leaves on the lower part of the ſtalk are almoſt as large as thoſe of the common ſort, but thoſe on the upper part of the ſtalk and branches are very ſmall, and ſit cloſe to the ſtalk.

It grows naturally in the Levant, and was diſcovered by Sir George Wheeler on mount Sipylus; he ſent the ſeeds to the Oxford garden; [where it was cultivated in 1699, by Mr. Jacob Bobart. It flowers from june to ſeptember[4].

4. Root ſometimes as large as the thumb, woody, about a foot long, brown without, reddiſh within, with twiſted fibres. Stems eight or nine inches high, glaucous, ſimple or branched. Leaves round or oval, nine or ten lines in length, not unlike thoſe of n. 2. ſome of them thick, fleſhy and ſmooth, others thinner and ſlightly villoſe, ſome are inſipid, others ſharp, ſome odoriferous, others without ſcent; none of theſe leaves diminiſh, except towards the top of the branches and ſtems, which commonly divide into two ſpikes, or are terminated by one only; each ſpike is fifteen or twenty lines long, and five or ſix wide, formed by four rows of ſcales, of a pale purple colour, oval pointed, four or five lines long; ſometimes they are pale green with

[1] Hort. kew. [2] Idem. [3] Idem.

purple borders: the flowers expand ſucceſſively from the axils of theſe, nine or ten lines long: the tube is half a line in diameter, white, and ſpreads into two lips, the upper two lines and a half long, blunt and folded; the lower of the ſame ſize, rounded and divided into three blunt ſegments, terminated behind by a ſpur half a line in length. Stamens longer than the upper lip, but of the ſame colour: anthers twin. Calyx tubular, two lines and a half long, pale green; at the bottom of it two or three very ſmall blackiſh ſeeds ripen, one of the embryos being always abortive. The ſeeds vegetated well in the Royal Garden at Paris, and the plant was not altered by culture [b].

Native of the iſland of Amorgos. Introduced in 1788 by the late John Sibthorp, M. D. It flowers in auguſt [c].

Mr. Miller applies this name of Tournefort's to his twelfth ſort, which he ſays] is undoubtedly a variety produced from the intermixing the farina of the Cretan Dittany with that of Mount Sipylus, for the plants in the garden belonging to the Company of Apothecaries were accidentally produced from the ſeeds of one ſpecies, where both ſorts ſtood near each other in the botanic garden of John Browning, Eſq. Maſter in Chancery, at Cheliea; the ſeeds were dropped from the plant into the border between the two ſorts, ſo that it is uncertain from which ſpecies they came; but as the ſtalks and heads of flowers bear a greater reſemblance to the Dittany of Mount Sipylus, we may ſuppoſe it aroſe from the ſeeds of that, impregnated by the farina of the Cretan Dittany, which grew near it; for the under leaves of this are round, of a thick texture and woolly, ſo nearly reſembling thoſe of the Cretan Dittany as not to be diſtinguiſhed from it, but the ſtalks riſe full as high as thoſe of the Dittany of Sipylus, but branch out more their whole length; they are of a purple colour and hairy: the lower leaves on the ſtalk are much larger than thoſe of Mount Sipylus and are hairy, approaching to thoſe of the Cretan Dittany, but not ſo thick or woolly; the upper leaves are ſmooth, and approach to thoſe of the other ſort, but are larger, as are alſo the ſpikes of flowers, and the ſealy leaves which cover the flowers are larger and of a deeper purple colour.

Mr. Miller had alſo dried ſamples of another variety, which aroſe from ſeeds in the Leyden garden: theſe ſeeds were ſent from Paris, by the name which Tournefort gave to that which he found in the Levant. The leaves of this are as large as thoſe of the Dittany of Crete, but not ſo thick or woolly; the ſtalks riſe more like thoſe of the Dittany of Mount Sipylus, but branch out wider at the top; the flowers grow in cloſer cluſters, and do not hang downward: they are ſmall, ſhaped like thoſe of the former ſort, and flower at the ſame time.

By the character which Linneus gave to the Cretan Dittany, it may be ſuppoſed he had not ſeen the true ſort, for it better ſuits the variety. All the leaves of the true Dittany are very thick and woolly, even thoſe which are ſituated immediately below the flowers, whereas the lower leaves only are ſo in his character.

[Mr. Miller's hybridum ſeems to be only a variety of the ſecond ſort, and by no means the ſame with this of Tournefort.]

5. This is the Origanum of Crete, directed to be uſed in medicine; but there has been great confuſion among botaniſts in diſtinguiſhing the ſpecies. It riſes a foot and half high. The leaves are ovate and hoary, with a ſtrong aromatic ſcent. The flowers grow in long, erect, bunched ſpikes at the top of the ſtalks, having membranaceous bractes between, twice the length of the calyx. The flowers are ſmall and white, like thoſe of common Origanum. It flowers in july, but ſeldom perfects ſeeds in England.

[According to Gronovius, the leaves are ovate, acute and ſmooth, with the veins rugged; according to Linneus, in the Amoenitates, they are ovate, blunt, rugged and quite entire; the ſpikes cluſtered, compact and ſmooth.

[b] Tournef. voyage. [c] Hort. kew.

Haller ſays that he compared the dry plant with the ſpecimen in Caſpar Bauhin's herbarium; that it agrees with it in the ſpikes, which are long, cylindric, and have bractes ſuch as are in the common ſort, ovate-lanceolate, but heaped and imbricate, to twenty-four in a ſingle ſpike. In the Swiſs ſpecimen the leaves are more acuminate; in the Cretan ſpecimen they are a little rounder. The Cretan may be a variety of the Swiſs with larger bractes, and the flowers are ſometimes larger.

Native of the South of Europe, about Baſil, and in Paleſtine on mount Libanus, the mount of Olives, and between Rama and Joppa. China near Canton, according to Loureiro.

6. This is a perennial plant, with ſeveral rod-like, woody, long ſtems, putting forth branchlets at intervals. Leaves ſmaller than thoſe of Cretan Marjoram, leſs hoary, and not ſo round, but rather oblong, acuminate, nerved, and ſomewhat lanuginoſe. Scaly heads terminate the ſtems and branches. It exhales a very fragrant ſmell.

Found by Sir George Wheeler abundantly at Smyrna, on the mount upon which the citadel is built [d]. Linneus adds Crete, and Tournefort gives it the epithet *creticа*.]

7. Root perennial; from which ariſe many branching ſtalks a foot and half high, hairy, and inclining to a purpliſh colour. Leaves ovate, obtuſe, hairy, reſembling greatly thoſe of Sweet Marjoram, on ſhort footſtalks. Flowers in ſpikes about two inches long, ſeveral ariſing together from the diviſions of the ſtalk. Flowers ſmall, white, peeping out of their ſcaly covers.

[Linneus remarks, that it has the habit of Common Marjoram, but that the ſpikes are a finger's length, looſely imbricate. It differs from *O. creticum*, in having the bractes longer than the calyxes, and the ſpikes peduncled.]

It grows naturally in Greece and the warm parts of Europe. It is now commonly known by the name of Winter Sweet Marjoram, but was formerly called Pot Marjoram. It is chiefly cultivated for noſegays, becauſe it comes ſooner to flower than Sweet Marjoram. There is a variety with variegated leaves.

[Mr. Miller cultivated it in 1731 [e]. According to Loureiro, it is a native of China and Cochinchina.

8. Root perennial, creeping, horizontal, brown, tufted with numerous fibres. Stem a foot, eighteen inches or near two feet in height, upright, ſomewhat woody, a little downy, and often tinged with purple: branches oppoſite, upright, more tender than the ſtalk, in other reſpects ſimilar. Leaves ovate, pointed, finely and thinly toothed, above nearly ſmooth, beneath downy, dotted on both ſides, the edge finely ciliate, ſpreading. Petioles downy. The axils of the leaves, in the cultivated plant, bear numerous ſmaller leaves. Bractes ovate, ovate-lanceolate or lanceolate, ſeſſile, concave, entire, more deeply coloured than the corolla, appearing downy when magnified [f]. Calyx nearly equal, the mouth cloſed with briſtly hairs, which at firſt lie parallel to the ſides, but when the corolla falls off they ſtand out cloſing up to the mouth; without beſet with ſhort fine hairs, and minute white ſhining globules. Corolla pale red, hairy, the middle ſegment rather longer than the reſt. Stamens as long as, or longer than the corolla, but in ſome ſpecimens ſhorter, and then the anthers appear to be deſtitute of pollen [g].

Wild Marjoram is an aromatic and ornamental plant, growing wild in thickets and hedges, chiefly in a calcareous ſoil; and flowering from the end of june through auguſt.

The dried leaves, uſed inſtead of tea, are exceedingly grateful; the are alſo uſed in fomentations: the eſſential oil is ſo acrid, that it may be conſidered as a cauſtic, and is much uſed with that intention by farriers; a little cotton moiſtened with it, and put into the hollow of an aching tooth, frequently relieves the pain. The country people uſe the tops to dye woollen cloth purple [h]. It alſo dyes linnen of a reddiſh brown

[d] Ray. [e] Hort. kew. [f] Curtis. [g] Withering. [h] Idem.

colour;

colour; for this purpose the linnen is first macerated in alum water and dried; it is then soaked for two days in a decoction of the bark of the crab-tree; it is wrung out of this, boiled in a ley of ashes, and then suffered to boil in the decoction [1]. According to the Swedish experiments, goats and sheep eat it; horses are not fond of it; and kine refuse it.

The leaves vary in shape from ovate to ovate-lanceolate and ovate-cordate.] There is a variety with white flowers and light-green stalks; and another with variegated leaves. It is sometimes cultivated in gardens, and is by some called Pot Marjoram; being commonly used in soups.

[Our Wild Marjoram is found not only in most parts of Europe, but also in the rocky parts of Canada, where the bractes are of a very high colour [2]. I have placed three of Mr. Miller's species as varieties under this.

9. Pot Marjoram has the habit of Sweet Marjoram (O. Majorana), but it is woody. Stems with long spreading hairs. Leaves small, subsessile, acute, thinly serrate, tomentose on both sides; with rudiments of branches from the axils. Spikes heaped, as in O. Majorana, but oblong, by threes on each peduncle, the middle one sessile, villose: flowers white [3].]

Stems perennial, woody, a foot and half high, dividing into many small branches. Leaves a little larger than those of Marjoram and woolly. Flowers small, white, just emerging out of their scaly covers. They appear in july, but seldom perfect seeds in England.

Native of Sicily, about Syracuse. [Cultivated in 1759, by Mr. Miller [4]. Certainly not an English plant. We do not know what Mr. Hudson took for it.

10. This has the habit of O. Majorana. Leaves roundish-ovate, acute, with wandering hairs scattered over them. Racemes from the axils. Corymb terminating, brachiate with longer branches. Spikes generally every where three, terminating, long, erect, four-cornered, villose.

Place of growth uncertain [5]. According to Loureiro it grows wild in Cochinchina.

11. This also has the appearance of the next species, but is more rigid. Leaves without any manifest petioles, very thick, tomentose, ovate not obovate, white. Stem purple, with a few villose hairs scattered over it. Heads very hirsute, triternate; the last sessile, terminating the stem and branches.—Native of Crete [6].

12. Root biennial, brown, with many long tough fibres. Stems numerous, woody, branched, a foot and half high. Leaves downy, entire, pale green, petioled. Flowers small, white, appearing successively between the bracteal leaves, which are numerous, and form roundish compact terminating spikes. Calyx tubular, divided at the brim into five pointed segments. Tube of the corolla funnel-shaped, divided at the border into two lips, the upper erect and roundish, the under cut into three pointed segments [7].]

It begins to flower in july, at which time it is cut for use, and is then called Knotted Marjoram, from the flowers being collected into roundish close heads like knots.

Sweet Marjoram was cultivated here in 1597, as appears from Gerarde's Herbal [8]. Loureiro says it grows in China and Cochinchina, but is rare, and perhaps introduced from abroad.

It is thought to be the Σαμψυχος or Amaracus of the ancients. The place of which it is a native has not been ascertained.

The leaves and tops have a pleasant smell, and a moderately warm aromatic bitterish taste. They yield a considerable quantity of essential oil, amounting, according to Beaume, to fifteen ounces from one hundred and fifty pounds of the recent plant. This oil, on being long kept, assumes a solid form. The medicinal qualities of this plant agree with those of Wild Marjoram; but being much more fragrant, it is deemed more cephalic, and better adapted to those complaints known by the name of nervous, and may be therefore employed with the same intentions as Lavender. It is directed in the composition of Pulvis sternutatorius in the London and Edinburgh Pharmacopœias, with a view to the agreeable odour which it gives to the Asarabacca, rather than to its errhine power, which is very inconsiderable. In its recent state we are told that it has been successfully applied to schirrous tumours of the breasts [9].

Our English name is evidently corrupted from *Majorana*; by our old herbarists it is written *Marjerone*; and Gerarde says, of the best sort it was called *Majorane*.]

[1] Haller. [2] Linn. [3] Idem. [4] Hort. kew. [5] Linn. [6] Idem. [7] Woodville. [8] Hort. kew.

PROPAGATION AND CULTURE.

1. It is increased by slips or cuttings, planted in a border of good earth in any of the summer months, shaded and duly watered. Plant them in small pots filled with light kitchen-garden mould, when they are well rooted, and place them in the shade till they have taken new root; then remove them to an open situation till the end of october, when they must be placed under shelter. Under a hot-bed frame, where they may be protected from hard frost, and have as much free air as possible in mild weather, they will thrive better than if more tenderly treated.

2. Dittany of Crete is increased in the same manner, in pots or a shady border, covering the slips or cuttings close with a bell-glass or hand-glass, and now and then refreshing them with water, but not too much. The following spring some of the plants may be shaken out of the pots, and planted in a warm border, in a dry soil, where they will live through common winters; but being liable to be killed by severe frost, it will be proper to keep a few plants in pots, to be sheltered in winter.

3, 4. May be propagated and treated in the same manner.

5, 6. Are increased by parting the roots in autumn, but must have a dry soil and a warm situation.

7. Winter Sweet Marjoram is hardy enough to thrive in the open air in England, in a dry soil, and is generally propagated by parting the roots in autumn.

8. Common Marjoram, with all its varieties, is propagated in the same manner; or it will rise plentifully from scattered seeds.

9, 10, 11. May be increased by cuttings or slips.

12. Sweet or knotted Marjoram is propagated by seeds, which are generally imported from the South of France or from Italy, for they seldom ripen in England. Sow them on a warm border towards the end of march; and when the plants are about an inch high, transplant them into beds of rich earth, at six inches distance every way; watering them duly till they have taken new root: after which they require only to be kept clean from weeds.

33. Ornithogalum undulatum.
Thunb. prodr. cap. 62.
Leaves enſiform waved, ſcape ſubcylindrical, raceme comoſe ſhort.

34. Ornithogalum punctatum.
Thunb. prodr. cap. 62.
Leaves enſiform channelled, ſcape cylindrical, raceme very long comoſe, flowers remote.

35. Ornithogalum aureum. *Golden Star of Bethlehem. Curt. magaz.* 190.
Leaves ovate-lanceolate edged with white flowers racemed cluſtered, filaments placed on an emarginate nectary.

DESCRIPTIONS, *&c.*

1. The plant altogether reſembles O. luteum, but the peduncle is undivided and one-flowered. Flower half the ſize of Tulipa ſylveſtris, but three times as big as that of O. luteum. Petals lanceolate, blunt-iſh, yellow, green underneath. Filaments and anthers yellow, ſhorter than the petals. Germ oblong. Style the ſame length with the ſtamens. Stigmas three, blunt, all yellow. Leaves on the ſtem two, one above, both the length of the flower or the plant, double the breadth of O. luteum. Found in Siberia by Laxman[1]. Introduced in 1781, by Baron Claes Alſtroemer[2].

2. Leaves ſmooth, ſcarcely a finger's length. Scape ſhorter than the leaves. Peduncles ſcarcely half an inch long. Bractes oblong, acuminate, very ſhort. Petals four lines in length, white; the three outer with a green keel. Filaments ſhorter by half than the petals, ſnow white, alternately wider and narrower. Anthers pale yellow. Found by Maſſon at the Cape of Good Hope, and introduced in 1744. It flowers here in auguſt[3].

3. Bulb ſolid, having ſmaller bulbs joining to it. Root-leaves (ſometimes five) ſoft, keeled, or convex on the outſide and channelled within, with a white ſilvery ſtreak, from one to two lines in width, and above a foot in length, linear, bright green. Scape upright, round, very ſmooth, a long ſpan or a foot in height, terminating at top in alternate peduncles, very long and broad, all together forming a ſort of corymb, reſembling an irregular umbel, but not ſpringing from the ſame point; the lower ones being longer the flowers are all nearly of the ſame height; they are one-flowered, and each has a white, membranaceous, lanceolate, very large bracte. Petals white, with a broad green ſtreak along the under ſide; lanceolate, in two rows, three appearing to be a little larger, near an inch long, and four lines wide. Filaments lanceolate, flat, fleſhy, every other broader; all ſimple, not three of them forked or emarginate, as deſcribed by Linneus, Haller, &c. Anthers pale yellow, two lines in length. Germ with ſix blunt angles. Stigma three-ſided, white, blunt. Capſule ovate, blunt[4].

Mr. Woodward remarks that this ſpecies is very improperly called *umbellatum*, as the flowers are in a moſt evident ſpike (or rather corymb), whereas in *O. luteum* they actually grow in an umbel.

Native of the ſouthern parts of Europe, Germany, France, Switzerland, Auſtria, Carniola, Italy; alſo of the Levant; in orchards, paſtures, vineyards, and thickets. With us it is a doubtful native, as many of the bulbous plants are. In the cloſes about Streatham in Surry. Stillingfleet obſerved it in Norfolk, Relhan in Cambridgeſhire, Sibthorp near Barton, and in Chriſt-Church meadows Oxfordſhire, and Mr. Robſon ſays it is plentiful in a field near Knareſborough, Yorkſhire. By Ledſtone Hall near Leeds in the ſame county. It flowers in april and may.

4. Root-leaves generally ſingle and longer than the ſtem, which is from four to ſix inches high. Stem-leaves ſometimes two, three or four, one very large, the other ſmaller, all unequal; fringed with fine white hairs. From theſe ariſe a few fruit-ſtalks, (three to ſeven)

[1] Linn. mant. [2] Hort. kew. [3] Idem.
[4] Pollich, Haller, Villars, Withering. Woodw. Mſs.

each supporting one flower, and forming an umbel. Petals in two ſeries, the inner greeniſh yellow, the outer entirely green [f].

Mr. Woodward has a ſpecimen from the banks of the Tees, in which from two bracteal leaves, ariſes a ſingle fruitſtalk, ſupporting one flower. He remarks that this plant is well figured in Flora Danica, only much too large. Gerarde *emac.* 165. 2. and Petiver, 66. 12. both repreſent it well. Moriſon's is a very bad figure.

The roots of this ſpecies have been uſed for food in times of ſcarcity in Sweden: thoſe of all the ſpecies are nutritious and wholeſome [a].

Native of moſt parts of Europe, in woods, paſtures, and moiſt ſandy places; flowering in april. With us in the meadows near Godalming in Surry. Woods near Aſhford-mill, and Fauler in Oxfordſhire. In ſeveral parts of the North, as in a meadow adjoining to the Copper-mills, Derby. Under Malham-cove; near Doncaſter, Yorkſhire; and Kendal, Weſtmoreland; woods on the banks of the Tees near Greta-bridge, and Bignal, Yorkſhire. In Northumberland. Found in Scotland by Sibbald.

5. This reſembles the preceding very much, but the petals are more acute [a]. Scopoli and Gmelin think that they are only varieties; and Haller allows that there is a great ſimilitude between them. The preceding has the flowers yellow and larger, on ſimple peduncles: the leaves are alſo wider and greener. This has ſmaller flowers, more numerous, greeniſh or aſh-coloured yellow, on ſubdivided peduncles; leaves ſmall, aſh-coloured green [b].

Leers diſtinguiſhes it from the common yellow ſort by the ſcape being roundiſh, the umbel ſhorter, the leaves of the involucre more and longer, the peduncles round ſomewhat branched pubeſcent, the petals ſix, eight or nine, of a golden ſhining yellow, ſpreading very much, ſharper, the three outer blunter, pubeſcent underneath, the piſtil ſubvilloſe commonly abortive, the bulbs or offſets heaped axillary bracted.

Krocker remarks, that it is readily known from the preceding by its growing in a tuft.

The Biſhop of Dronthem, who doubts whether this and the *luteum* be diſtinct, ſays that it is only half the ſize, that the root-leaf is very narrow, and filiform at the baſe, not ſo flat as that of *O. luteum*. One or two of the peduncles branched, but this is ſometimes the caſe in the *luteum*. The petals are acute, nay extremely ſo in both; but ſometimes both have them blunt. The roots, though ſmall, are eſculent [c].]

Mr. Miller ſays that the bulbs are not larger than peas, that one or two narrow keel-ſhaped leaves about five inches long of a grayiſh colour ariſe from them, that the ſtalk is angular, about four inches high, having two narrow keel-ſhaped leaves juſt below the flowers, which are diſpoſed in an umbel on branching peduncles, they are yellow within but of a purpliſh green on the outſide; *they* appear in may, and are ſucceeded by ſmall triangular capſules, filled with reddiſh uneven ſeeds.

[Native of Sweden, Norway, Denmark, Germany, France, Switzerland, Hungary, Italy, on the borders of fields.

6. Stem naked, a foot and half or two feet high. Flowers in a long ſpike on ſlender peduncles, each ariſing from a membranaceous half-embracing bracte, broad at the baſe, tapering to a point. Petals narrow, ſpreading, pale yellow within, green on the outſide with whitiſh margins [a].]

Bulb pretty large, with ſeveral long keeled leaves coming out from it and ſpreading on the ground; among theſe comes out a ſingle naked ſtalk about two feet long, ſuſtaining a long looſe ſpike of flowers of a yellowiſh green colour, on pretty long peduncles and ſpreading wide from the principal ſtalk; petals narrow, making little appearance. The flowers have an agreeable ſcent, and appear in may: when the ſeed-veſſels are formed, the fruit-ſtalks become erect, and approach to the ſtalk. The ſeeds ripen in auguſt.

[f] Woodw. Mſt. Robſon in With. [a] Linn. ſuec. & With. [a] Linn. [b] Villars. [c] Fl. norv. 147. [d] Woodw. Mſs.

[Native of ſome parts of Europe, in paſtures. Between Bath and Bradford, near Little Aſhley. Between Bath and Warminſter, three miles from Briſtol in the way to Bath, and near Queen Charlton in Somerſetſhire. Half a mile from Chicheſter ſouthgate, in a meadow.

7. Height almoſt three feet. Bractes not embracing, very much tailed, the length of the pedicels. Petals very narrow, concave, wider at the tip, ſulphur-coloured, with a green dorſal nerve. Stamens not narrower one than another, but only alternately ſhorter. Flowers from fifty to ſixty.

It is eaſily known from O. narbonenſe, to which it is nearly allied, by the leaves being ſcarcely a palm in length and very narrow, whereas in the other they are a foot and half long, and an inch wide [a].

According to Scopoli, the principal difference conſiſts in the flowering peduncles of this ſpreading very much, but the fruiting peduncles erect and preſſed or parallel to the ſcape. Beſides the root is eaſily pulled up; the leaves three or four, channelled, turning yellow and withering, whilſt the plant is flowering; ſcape round, naked, two feet high, terminated by flowers in a long raceme and ſpreading; filaments alternately ſhortly bifid when examined by a glaſs. Capſule ovate, terminated by the ſtyle, and having five ſeeds in a cell.

Native of the South of Europe. Introduced about 1771. It flowers in april [b].

8. This is ſmaller than the preceding, with longer wider leaves. Gerard and others regard it as a variety of that.

Native of the South of France, Spain, Italy, Germany and Siberia.]

9. Bulb large. Root-leaves ſeveral broad ſword-ſhaped, ſpreading on the ground. Stalk thick, ſtrong, between two and three feet high, bearing a long ſpike of large white flowers, upon long pedicels.

[The leaves are a foot long, and more than two inches in breadth [a].

Ray, who cultivated it in his little garden at Cambridge, remarks that in the flowers which opened firſt the tips of the petals were green, whereas Cluſius ſays they are all of a ſnowy whiteneſs without any green nerve; that the pedicels are two inches long; and that the leaves begin to wither before the flowers open, nay are quite dried up if the plant be late in flowering. Cluſius counted above one hundred flowers on a ſpike.

Native of Egypt and Arabia. Cultivated here in 1629, as appears from Parkinſon. It flowers in june [b].

10. This ſpecies was received by Profeſſor Jacquin from the Cape of Good Hope, and is figured in the third volume of his Hortus Vindobonenſis. The bulb is ovate, whitiſh, with cloſely compacted ſcales, and of the ſize of an egg. Leaves about a foot and half long, and an inch and half broad, glofſy, acute, of a bright green, ſomewhat erect, thickiſh, ſeveral in number. Stem erect, *cylindric*, of the thickneſs of a finger, and two feet high, terminating in a conic, thick ſpike, which is gradually diſplayed, and at length changes into a lax, cylindric raceme of almoſt a foot long. The bractes, which are ſeated at the baſe of every footſtalk, are lax, of a pale green, ſubulate; the lower ones nearly four inches long; the upper ones gradually ſhorter. Footſtalks numerous, and about two inches long: flowers white, inodorous, with obtuſiſh petals each ſtreaked behind with a green ſtripe or line. Stamens ſhorter than the flower, wideſt at bottom. Anthers oblong, yellow, incumbent. Piſtil green. This ſpecies may perhaps be the ſame with the O. bracteatum of Thunberg prodr. plant. capenſ. p. 62.

11. Beſler deſcribes this ſpecies as having a foot conſiſting of two connate bulbs, with their fibres; leaves narrow, thick, porraceous, reflex. Stems aſſurgent, cloathed on the upper part with numerous milk-white flowers, of a medicated odour. Stamens purple with yellow anthers.—See Beſl. Hort. Eyſt. 1. Ord. 5. Plant. Vern. t. 14. fig. 3.]

[a] Gouan. Illuſtr. [a] Hort. kew. [b] Linn.
[b] Hort. kew.

12. This

12. This has a very large oval bulb, from which arife ſeveral long keeled leaves, of a dark green colour; in the middle of theſe ſprings up a naked ſtalk near three feet high, terminated by a long conical ſpike of white flowers, on pretty long pedicels.

[Capſule ſuperior, ovate-pyramidal, membranaceous, thin, whitiſh, three-grooved, having the partition in the middle. Receptacle none, beſides the central margin of the partitions, to which the ſeeds are faſtened horizontally in a double row. Seeds ſix or eight in each cell, few of them ripening, ovate-globular, beaked with a tubercle at the navel, ſomewhat wrinkled, black [1].]

It grows naturally upon the hills in Spain and Portugal, but has been long cultivated in the Engliſh gardens by the name of Star of Bethlehem. It flowers in june, and the ſeeds ripen in auguſt. [Cultivated by Mr. Miller in 1739 [2].

13. Bulb ovate, the ſize of a hazel nut. Leaf upright, flat, broad-lanceolate, blunt, naked, ciliate, ſheathing the ſcape at the baſe. Scape upright, round, longer than the leaf, terminated by a few-flowered raceme. Flowers peduncled, alternate. Bracte equalling the pedicel, embracing the baſe of it, awl-ſhaped. Corolla dirty yellow, ſpreading very wide; petals lanceolate, blunt. Filaments broad-lanceolate, quite entire, alternately wider and narrower. Anthers verſatile, yellow. Germ roundiſh three-cornered, with the corners channelled. Theſe corners are white from the baſe, and being placed as it were on the germ, terminate in a ſubulate-three-cornered ſtyle; the deep ſinuſes between theſe are green and melliferous. Stigma ſimple. Thunberg ſent the bulbs from the Cape of Good Hope, and it flowered in the garden at Lund in 1776 [3].

I do not find this plant in Thunberg's prodromus of Cape plants, publiſhed in 1794.

The Ornithogalum unifolium of Parkinſon is the Scilla unifolia of Linneus.]

14. Bulb large. Many long keeled leaves ariſe from it, which embrace each other at the baſe; they are of a deep green and ſtand erect. [Bractes embracing, cordate. Stamens connate [4]. Stem eighteen inches high, ſmooth, naked, ſlender. Flowers the ſize of thoſe of Narciſſus, on long pedicels; petals white, ſmelling like Coriander ſeed [5].

Native of Arabia, according to Miller; of Alexandria in Egypt and the Cape of Good Hope, according to Linneus. Cluſius ſays that in his time it was ſent every year to Vienna from Conſtantinople.—In the Kew catalogue it is ſet down as a native of Egypt and Madeira; Parkinſon ſays it was often ſent him out of Turkey, and likewiſe out of Italy, and that he had two roots ſent him out of Spain by Guillaume Boel, which, as he ſaid, he gathered there.

It flowers here in march and april.] Miller ſays that he had never ſeen the flowers, though he tried many ways to procure them; that the bulbs are frequently brought over from Italy for ſale, but that he had not heard of any having flowered. [Cluſius does not ſay that he never ſaw but one root flower; but that the bulbs did not flower at Vienna unleſs they came freſh from Conſtantinople. Parkinſon calls it the Great Starre-flower of Arabia; and Ray, Great Arabian Star-flower.

15. This ſpecies, variety *a*, is figured in Houttuyn. 12. t. 82. fig. 3. and Profeſſor Jacquin has figured variety *β* on pl. 28 of his Hortus Vindobonenſis. The whole plant is ſmooth. Leaves ſeveral, weak, long-lanceolate, ſharp and thickiſh. Stem a foot high, of the thickneſs of a gooſe-quill, and glaucous. Raceme erect, nearly ſix inches long, thick, and elegantly thyrſiform. Peduncles an inch long. Bractes at their baſes of the ſame length and lanceolate. Flowers ſnow-white, with a ſpot of brownith yellow at the baſe of each petal. Sometimes (but not always) each alternate petal is narrower than the reſt. Germ blackiſh-green. Flowers ſlightly odorous.—Received by Jacquin from the Cape of Good Hope.

The variety *a*, figured in Houttuyn, ſeems chiefly to differ in being ſomewhat thinner or narrower in all its parts than the plant repreſented by Jacquin, and in having yellow flowers.

16. The whole plant is ſmooth. Leaves a foot and half long, an inch and half wide. Scape round, three feet high. Raceme a foot and half long: peduncles ſcattered, ſpreading during flowering, ſcarcely an inch in length. Bractes lanceolate, awl-ſhaped, the length of the peduncles, membranaceous. Petals half an inch long, white with a longitudinal green fillet. Filaments ſhorter than the petals, white. Style three-ſided, white, the length of the ſtamens.

Native of the Cape of Good Hope. Found there by Mr. Fr. Maſſon. Introduced in 1774. It flowers from february to auguſt [6].]

17. This has a pretty large, compreſſed bulbous root, from which come out many long narrow keeled leaves, of a dark green colour. The ſtalks are very thick and ſucculent, about a foot high, ſuſtaining ten or twelve flowers in a looſe ſpike, each hanging on a footſtalk an inch long. Petals white within, but of a grayiſh green on their outſide: within the petals is ſituated the bell-ſhaped nectarium compoſed of ſix leaves, out of which ariſe the ſix ſtamens, terminated by yellow anthers. As the capſules grow large, they are ſo heavy as to weigh the ſtalk to the ground. [They are ovate, three-cornered, black. Seeds globular, the ſize of Radiſh ſeed, without any tubercle at the navel, with ſmall excavations all over them, of a blackiſh brown colour [1].

Native of Italy.] It grows in great abundance in the kingdom of Naples, and is now become very common in England. The roots propagating ſo faſt by offſets and ſeeds as to become troubleſome weeds in gardens; and where the roots have been thrown out, they grow on dunghills and waſte places plentifully. [It is alſo become a denizon of Switzerland, is common in the meadows near Berne, and in the orchards about Geneva. I found it in april 1779 at Chatelaine. It was cultivated in England in 1633. Linneus ſays it was known at Naples about 1570. It flowers in april and may.]

18. This has an irregular tuberous root, varying greatly in form and ſize, covered with a dark brown ſkin, from which ſpring ſeveral leaves, upon pretty long foot-ſtalks, and having ſeveral longitudinal veins like Ribwort Plantain. The flower-ſtalks are ſlender, naked, and about a foot high, ſuſtaining ſeveral ſmall greeniſh-white flowers, formed in a looſe ſpike, ſtanding upon long ſlender pedicels. They come out in november, make but little appearance, and are not ſucceeded by ſeeds in England.

Native of the Cape of Good Hope. [Linneus remarks, that the ſtamens are connected into a cylinder.

19, 20, 21, 22, 23. Found at the Cape of Good Hope by Thunberg.

24. This is a very diſtinct plant with a ſimple one-flowered ſtem; leaves alternate filiform, all having a little bulb in the axils; flowers yellow, like thoſe of *O. minimum*, with awl-ſhaped petals.

Found by Pallas in muddy places that are dry by the Wolga and Jaick.

25. This reſembles O. minimum very much, but is quite diſtinct. Sheath looſe, fibrous, netted, ferruginous, ſurrounding the leaf and ſcape as it were with a cowl. Root-leaf ſlender, recurved, linear, channelled, longer than the ſcape and cyme. Stem-leaves three or four, as many as the flowers, of the ſame form with the root-leaf. Cyme of the ſame diviſion and number of flowers as in O. minimum. Flowers larger and handſomer than thoſe of O. luteum. Outer petals quite awl-ſhaped. The whole plant, except the flower, covered with a very ſmall hoary ſhaggineſs.—Found by Pallas in dry ſpots near Aſtrachan [4].

26. Bulb conical, fleſhy, white, a little larger than a hazel nut. Leaves radical, linear, flat, ſmooth, upright, a finger's length, ſhorter than the ſcape. Scape round, ſmooth, upright, a foot high or more. Flowers

upright,

[1] Gartner. [2] Hort. kew. [3] Retzius. [4] Linn. [5] Cluſius. [6] Hort. kew. [1] Gartner. [2] Linn. ſuppl.

upright, opening one after another, in a raceme of a finger's length or upwards. Bractes linear, ſhrivelling but permanent, ſhorter than the peduncles; which are capillary, erect, one-flowered, a line in length. Corolla blue-purple, ſpreading, permanent: petals lanceolate, a line in length. Filaments awl-ſhaped, erect, white, the length of the corolla, alternately broader at the baſe. Anthers ovate, twin. Germ ſuperior. Style awl-ſhaped, erect, white, the length of the corolla. Stigma ſimple, blunt, white. Capſule ovate, acute, three-ſided, ſix-ſtreaked, ſomewhat villoſe.

Native of Japan, about Jedo, Nagaſaki, &c. flowering in auguſt and ſeptember [1].

27. Bulb ovate, tunicated, an inch and half long. Leaves radical, ſubulate-linear, ſtrict, channelled, ſmooth. Scape quite ſimple, two feet high, ſtraight, round, many-grooved, naked. Flowers ſmall, violet, on ſhort pedicels. Bractes lanceolate, ſmall, permanent. Corolla inferior, deeply ſix-parted, erect. Stamens equal, entire, three alternate ones wider at the baſe. Capſule triangular-ovate, with one ſeed in each cell.—Native of China about Canton.

It is nearly allied to the preceding, but the flowers are by no means in a branched or racemed ſpike. The petals are neither diſtinct nor very ſpreading. The leaflet under each flower involves it, and is therefore rather a ſpathe than a bractе [2].

28, 29, 30, 31, 32, 33, 34. Found at the Cape of Good Hope by Thunberg [3].

35. Bulb whitiſh, reſembling in ſhape and ſize that of *Lachenalia tricolor*; from this ſpring three or four ſmooth, ſomewhat fleſhy, upright, dark-green leaves, about half an inch wide, and three or four inches long, edged with white, and, if magnified, appearing fringed with very fine villoſe hairs. Stalk naked, from eight to twelve inches high, ſupporting many flowers, which ſpring from the axils of large, hollow, pointed bractes, and opening one after another, keep the plant a conſiderable time in flower; they are uſually of a bright orange or gold colour, but ſometimes paler. All the filaments are dilated at the baſe, or rather ſit on a white glandular nectary, emarginate on the outſide.

Native of the Cape of Good Hope. Introduced by Meſſrs. Lee and Kennedy, a few years ſince. It flowers in january and february, and continues for ſeveral months [4].

Jacquin has figured five new ſpecies (giganteum, ſcilloides, revolutum, juncifolium, barbatum) in t. 87, 88, 89, 90, 91. of a magnificent work entitled Hortus Schoenbrunenſis.]

PROPAGATION AND CULTURE.

Several of theſe plants (3, 4, 5, 6, 7, 9, 12, 14, 17) are cultivated for ornament in the Engliſh gardens, and are hardy bulbs. They are propagated by offſets, which their roots commonly produce in great plenty. The beſt time to tranſplant them is july or auguſt, when their leaves are decayed; for if they are removed late in autumn, their fibres being ſhot out, they will be apt to ſuffer on being diſturbed. They ſhould have a light ſandy ſoil, not over-dunged. They may be mixed with other bulbs in the borders of the pleaſure-garden; and need not be tranſplanted oftener than every other year: for if they are taken up every year, they will not increaſe much, and if they are ſuffered to remain much longer unremoved, they will have ſo many offsets as to weaken the blowing roots. They may alſo be propagated from ſeeds, but the plants will not flower under three or four years.

The 3d, 4th, 5th, 14th and 17th, have in general no great beauty, but thriving in any ſituation, a few plants of each may be admitted for variety. The 3d, 5th and 17th will thrive in ſhade, but the 4th ſhould have an open ſituation. The 14th multiplies ſo faſt by offsets as to become a troubleſome weed.

The Cape ſorts (2, 15, 16, 18—23, 28—35) are alſo propagated by offsets, but being too tender to thrive in the open air, the roots muſt be planted in pots filled with light earth, and in autumn placed under a hot-bed frame, where they may be ſcreened from froſt, and in mild weather enjoy the free air. In the beginning of july the leaves and ſtalks generally decay, and then the roots may be taken up, and laid in a dry cool place till the end of auguſt, when they muſt be planted again.

Leaves in fours, flowers folitary.

DESCRIPTIONS, &c.

1. Common Bird's-foot has an annual ſlender root, nearly as long as the ſtem, with few long whitiſh lateral fibres. Stems ſeveral, trailing, from one to ſix inches in length, ſimple, round, pubeſcent. Root-leaves numerous, proſtrate, ſometimes on ſhort petioles: thoſe on the ſtem alternate, ſeſſile. Leaflets ovate or elliptic, oppoſite or alternate, ſomewhat keeled, appearing hairy when magnified, ſometimes blotched with purple; from three to fourteen pairs, uſually from ſix to nine, generally terminated by an odd one, which is ſmaller. Flowers ſmall, one to five in a bunch, commonly two or three, terminating, oppoſite to a leaf; on peduncles nearly of the ſame length with the leaf. Corolla variegated with white, red and yellow; ſtandard reddiſh white, marked with crimſon lines, ſlightly notched at the end, the claw yelloviſh brown; wings white with a reddiſh tinge; keel pale ſtraw-colour: ſometimes it is entirely yellow. Calyx hairy. Legume with croſs diviſions, ſeparating at the joints. Seeds about ſix, one in each joint. It is an elegant little plant, with pretty flowers, and ſingular ſeed-veſſels reſembling the claws of a bird, whence its name. It is not uncommon on dry heaths, commons and downs, on banks and by road ſides, eſpecially in a gravelly or ſandy ſoil: and flowers from may to ſeptember. It varies much in ſize, and has ſometimes little knobs adhering to the roots; but this is common in leguminous plants [a]. Hence authors have diſtinguiſhed it into three, and Mr. Miller into two ſpecies.]

2. The root of this runs deep into the ground, ſending out a few ſmall fibres on the ſide; the ſtalks are about ſix inches long, and do not lie flat on the ground like the preceding: the leaves are compoſed of ten or twelve pairs of narrow hairy leaflets, with an odd one at the end; the flowers grow in ſmall bunches at the ends of the branches, they are yellow, and are generally ſucceeded by two flat pods not much more than an inch long, turned inwards like a bird's claws.

[According to Linnæus, the plant is tomentoſe; the leaflets ſeſſile; the peduncles ſhorter than the leaf; and the flowers commonly two.

It is an annual plant, native of the South of Europe, flowers in june and july, and was cultivated by Mr. Miller in 1731 [b].

3. Root whitiſh, round, gradually ſharper, fibrous, an inch and half in length. Stems branching, ſuffruticoſe, erect, very ſmooth, three or four inches high. Leaves unequally pinnate; pinnules nine ovate, the two lower orbiculate. Stipules two ſcarioſe, ſhort, deciduous, conate at the baſe, and half embracing the ſtem. Flowers in a ſort of umbel: common peduncle an inch long, axillary, ſolitary, erect, longer than the leaf, ſupporting one, two or three ſmall flowers at the end. Calyx ſmooth, the two upper teeth very ſmall. Corolla deep yellow: ſtandard ovate, plaited, with lines of the ſame colour on the outſide; wings ovate, concave, approximating to and ſhorter than the ſtandard, the claws of all very ſhort; keel ſhorter with a bifid baſe. Germ oblong: ſtyle from recurved upright: ſtigma acute. Legume ſpiral, round. Seeds oblong, cylindrical, ruſeſcent.

It ſeems to be allied to Coronilla minima *Linn. Jacq. auſtr. t.* 271. but is abundantly diſtinct from it in the fruit.

Native of Spain, on hills, flowering and fruiting in june [c].]

4. This has many ſmooth branching ſtalks, which riſe near two feet high, and towards the top have trifoliate oval leaves ſitting cloſe, with two ſmall appendages. The lower leaves are often ſingle, and of a grayiſh colour, the middle leaflet being twice the ſize of the two ſide ones. The flowers ſtand upon ſlender peduncles, are yellow, and ſucceeded by taper pods two inches long.

[Root annual, round with ſeſſile tubercles, fibrous. Stems branched, half a foot high, herbaceous, erect or diffuſed. The whole plant is ſmooth. Leaves ternate, ſubſeſſile, the lateral leaflets orbicular, the middle one many times longer, ovate; all quite entire, bright green. Stipule oppoſite to the leaf, membranaceous, pellucid, ſheathing the ſtem, bifid at top. According to Linnæus, the leaves are ternate, or rather ſimple, petioled, with roundiſh ſtipules. Flowers umbelled: common peduncle axillary, ſolitary, longer than the leaf, naked, having from two to four flowers at top on very ſhort pedicels. The three lower toothlets of the calyx a little ſhorter than the other two. Corolla deep yellow: ſtandard ovate, entire, from erect reflex, with ſtreaks of a deeper colour, and a ſhort claw; wings ſhorter than the ſtandard, converging, concave; keel very ſhort, bifid at bottom. Germ linear: ſtyle ſetaceous, aſcending: ſtigma a brown terminating dot. Legume awl-ſhaped, round, pendulous, a little bowed, jointed. Seeds ovate [d].

According to Gærtner, the legume is about two inches in length, ſlender, awl-ſhaped, grooved and angular, bowed, jointed, but ſcarceiy ſeparating ſpontaneouſly at the joints; which are ſix or eight in number, oblong, one-celled, valveleſs; the laſt very ſmall, ſterile, clawed. Seeds oblong, ſomewhat compreſſed, ſlightly curved inwards, ſmooth, blackiſh: navel in the middle with a convex margin, faſtened to the edge of the cell at the outer future.

Native of the South of Europe, among corn and on the borders of fields. Cultivated in 1656 by Mr. John Tradeſcant, junior. It flowers in june and july [e].

5. This riſes to about a foot high, being erect, branched, and having twigs ſet with leaves alternately, on petioles three quarters of an inch long: leaflets ſmall, obcordate, yelloviſh green, ſmooth, with a prominent midrib on the lower ſurface. Flowers yellow, ſolitary from the upper axils [f].

Linnæus remarks, that having an opportunity of examining the plant only in a dry ſtate, he could not aſcertain whether it belonged to this genus or another, or whether it ought to form a new one.

Native of Jamaica.]

PROPOGATION AND CULTURE.

Theſe plants (except the fifth) are propagated by ſowing their ſeeds in the ſpring, upon a bed of light freſh earth, where they are to remain. When the plants come up, clear them from weeds, and thin them to about ten inches diſtance. In june they will flower, and the ſeeds will ripen in auguſt. There is no great beauty in them, but for the variety of their jointed pods they are preſerved in ſome pleaſure-gardens. They are annual plants, and periſh ſoon after the ſeeds are ripe.

Stem one-flowered, flower ſubſpathaceous.

DESCRIPTIONS, &c.

Juſſieu deſcribes the plants of this genus as fleſhy herbs of a ruſſet-colour, and faſtening themſelves to the roots of other plants. Root tuberous, imbricate with ſcales. Stem with alternate ſcales on it, generally ſimple. Flowers in terminating ſpikes, ſupported by bractles. Some of the ſpecies have a naked one-flowered ſcape, with a ſpathaceous flower, and are akin to the one-flowered Lathræas. Thunberg deſcribes a plant reſembling an Orobanche under the name of Phelypæa.—See Lathræa Phelypæa.

The Rev. Charles Sutton, who has beſtowed great attention on this genus, obſerves that theſe plants are not ſtrictly Paraſitic, as Epidendrum, Viſcum, &c. are; for they acquire ſuſtenance and ſtability not only from the ſoſter-plants to which they are attached, but alſo, and that in no ſmall degree, from the ſoil, into which they ſend forth radical fibres: that they exhibit an ungraceful formality from the want of leaves, and have their ſurface more or leſs beſet with minute pellucid glandulifcrous hairs, which project perpendicularly from the ſtems, ſcales, bractles, calyx and corolla, and are ſometimes found within the flowers, upon the very ſtamens and piſtils; theſe, according to the remarks of Guettard, have each an articulation at the diſtance of about two thirds from their baſe, and are tipped with a globular ſort of cup, bearing a viſcid gland: we may ſuppoſe them to be intended to carry off ſecretions, and to anſwer the purpoſes of leaves in performing the offices of reſpiration, &c. They have an acrid aſtringent taſte, and are rejected by all animals, except the minuter tribes of *Cimices* and *Thripſes*. He remarks laſtly that they are acotyledonous; for, when a ſeed has attached itſelf to the root of any living plant, to which it is ſuited by its nature to adhere, it ſwells into a pellucid ſcaly germ or bulb: and after throwing out around the point of adheſion ſeveral tender fibres, it puſhes up at once into a perfect plant, without any lateral lobes or cotyledons: developing firſt the ſcales and then the ſtalk, with a head of flowers concealed by bractles, in form reſembling a young head of Aſparagus: the flowers afterwards expand in ſucceſſion upwards, and the head becomes a ſpike. Adanſon has claſſed this genus among his Monocotyledones[f]; and Juſſieu among his Dicotyledones.

It is ſingular that theſe plants ſhould attach themſelves to ſhrubs and herbs of the claſs Diadelphia chiefly. Mr. Sutton ſays he has had no experience of

[f] Linn. tranſ. 4. 173.

the common notion of the baneſulneſs of Orobanche, in deſtroying the plants that feed it: the learned Dr. William Turner however affirms, that notwithſtanding he has not ſeen any Broom choked with this herb, that he has obſerved Clover to be utterly ſtrangled, and all the natural juice to be clean drawn out by it; he therefore calls it Choke-weed [s].

Dr. Smith having ſhown that no ſuch plant as Orobanche lævis exiſts [t], it is here omitted.

1. Our common Broom-rape has a large thick fleſhy oval ſcaly root, ſometimes bulbous, adhering to the woody roots of Broom and Furze for the moſt part; "the which (as Turner ſpeaks) it claſpeth "aboute with certaine lyttel rootes on everye ſide "lyke a dogge holdying a bone in his mouth." It is furniſhed with ſimple fibres, which are very brittle. Stems ſeveral, upright, fleſhy, hollow, channelled or angular, hairy, the thickneſs of a finger, from eight inches or a foot to eighteen inches in height, of a duſky yellow or ruſt-colour tinged with purple, cloathed with lanceolate ſcattered ſcales, which are much cloſer under ground. Flowers in ſpikes, at firſt pointed but afterwards cylindrical; they are ſeſſile, hairy, browniſh ruſt-colour, with a purpliſh tinge for the moſt part; when old they become ſtiff and of a dirty ruſt colour. Bractes lanceolate, acuminate, hairy, generally longer than the flowers. Calyx almoſt equal, hairy, two-leaved, the lateral one with the leaflets deeply bifid, the ſegments acute and unequal: varying with one leaf, four-cleft, poſteriorly divided to the very baſe.

Mr. Woodward deſcribes it with four teeth, the two outer longer and ſharper, the lower blunt; and Mr. Curtis, as one-leafed, divided into four ſegments, poſteriorly quite down to the baſe, and anteriorly more deeply than at the ſides; villoſe, whitiſh, the ſegments or teeth nearly equal and ferruginous. Corolla hairy: tube inflated upwards, curved in, ſlightly keeled at the back; mouth very open; border two-lipped, obſoletely toothletted; upper lip arched, blunt, entire, a little reflex; lower lip three-lobed, the lobes nearly equal, acute, flattiſh, the middle one hanging down. Filaments hairy at top, but quite naked at bottom, channelled, flat, the two ſhorter inſerted into the ſides, the two longer into the front of the tube, decurrent, recurved at top. Anthers twin, mucronate at one of the tips, adhering ſlightly, ſtraw-coloured; finally, together with the ſtyle, ſtanding out. Germ ſhining, ſomewhat hairy. Style alſo ſomewhat hairy, pubeſcent at top, purpliſh. Stigma two-lobed; the lobes globular, yellow, diſtant, divided tranſverſely along the middle. Capſule opening longitudinally. Seeds ſubturbinate, netted-cellular.—Mr. Curtis remarks, that the germ is marked anteriorly at the baſe with three prominent yellow glands, which pour forth plentifully a ſweet liquor; that it varies in ſize according to the ſize of the root it grows on; the ſtem being ſometimes almoſt as thick as the human thumb, and at other times not much larger than a wheat-ſtraw; and that the flowers vary much in their colour, but are moſtly dead purple or yelloviſh [u].

Such is our Engliſh Broom-rape, which is ſuppoſed not to be the Orobanche major of Linnæus and ſome other foreign botaniſts.

It is found in dry barren ground, generally at the roots of Broom or Furze, flowering in June.

2. Tall Broom-rape has a root like that of the preceding, adhering moſtly to the woody roots of *Centaurea Scabioſa* and Trifolium pratenſe. Stem alſo like that of the preceding, but taller. Flowers in a long ſpike, hairy, of a pale ruſſet or feuillemort colour, with darker veins, and pale yellow ſtigmas; afterwards they become ſtiff, ſomewhat compreſſed, and ruſt-coloured; ſometimes there are upwards of a *hundred of them in a ſpike*. Bractes as in the preceding. Calyx abbreviated, hairy, one-leafed, four-cleft, behind divided to the very baſe, with the ſegments lanceolate, acuminate, the two poſterior ones divaricating and longiſh; it is ſlightly ſtriated, dirty dirty white with pale-red lines. Corolla four-cleft hairy: tube cylindrical recurved, keeled at the back; mouth open; border two-lipped, unequal, fringed and curled; upper lip rounded, reflex, entire; lower three-lobed, the lobes equal and rounded. Nectary, four glands inſerted into the tube at the baſe of the filaments; which are ſmooth and naked in front, hairy at the baſe behind, the hairs not glandular; the two ſhorter filaments are inſerted into the ſides, the two longer into the anterior part of the tube. Anthers twin, mucronate at one of the tips, ſlightly adhering; finally ſtanding out along with the ſtyle. Germ ovate, ſmooth, naked. Style ſmooth, naked. Stigma two-lobed, obcordate, yellow, tranſverſely cloven along the middle. Seeds wrinkled, or obſoletely netted.

It is found among Clover, but not the firſt year; alſo on the borders of corn fields by *Centaurea Scabioſa* and *nigra*, *Scabioſa arvenſis*, &c. flowering in july and auguſt, and is no uncommon plant, but has been confounded with the preceding, although notwithſtanding they are ſimilar in general appearance, the difference is very diſcernible on a cloſer inſpection. There is reaſon to ſuppoſe it may have been noticed by Ray very early; for in his Cambridge catalogue, printed in 1660, he ſpeaks of having found the *O. flore majore* in a field of barley between Cambridge and Granchester, and in a corn field at Cherry-hinton, places in which this ſpecies is very likely to be found, as it grows among herbaceous plants, and never on the roots of Broom or Furze. He adds, alſo at Gamlingay, at the roots of Broom plentifully: here he undoubtedly means our *O. major*, for that is ſtill found there in great abundance. In his *Catalogus Plantarum Angliæ*, publiſhed ten years afterwards, he notices them thus; "ad radices geniſtæ, interdum et inter legetes [x]. The ſame notice is continued in the third edition of the Synopſis by Dillenius. They were not therefore ever conſidered as diſtinct ſpecies by theſe celebrated botaniſts.

3. Root bulbous, covered with ſcales. Stem upright, not branched, more than a palm in height, five lines thick at the baſe, ſomewhat angular, ſolid within, yelloviſh white, ſlightly pubeſcent; having inſtead of leaves ſcales, which are ovate, acuminate, yelloviſh white, ſcattered and ſeſſile. Flowers ſolitary, alternate, ſeſſile, erect, forming a looſe ſpike, cloſer at top; ſometimes there are two or three flowers together from a bracte, and about twenty-two in the whole ſpike; they are half an inch in diameter, above ſeven lines in width, and an inch in length. Bractes lanceolate, the length of the flowers, yelloviſh brown. Calyx whitiſh tinged with pale red, pubeſcent all over on the outſide, ciliate on the edge, conſiſting of two ſegments at the baſe irregularly toothed; the two lateral teeth larger than the others and ſharp. Corolla whitiſh, very pale purple at top, with a ſmall mixture of yellow, pubeſcent on the outſide: upper lip blunt, multifid, crenulate, waved, with pale purple veins on the inſide; lower lip trifid, waved, the edge brown, ſerrulate, lobed, the middle ſegment a little longer. Filaments bent, white, pubeſcent. Anthers yelloviſh brown. Germ ovate, ſmooth. Style pubeſcent. Stigma bifid, blackiſh, bent in. Capſule ovate, blunt, ſurrounded by the calyx and corolla, ſhrivelled and permanent. Seeds orbicular, ſmooth, duſky. It has a ſtrong ſmell of Cloves [y].

O. caryophyllacea agrees very nearly with *O. major* in habit and ſize, as well as in the appearance of the flowers; but differs in having the three ſegments of the lower lip obtuſe, and much more fringed and curled. The germ alſo is entirely ſmooth, which in *O. major* is hairy in the upper part, and the ſtyle is much leſs downy than in that ſpecies. But the moſt ſtriking mark conſiſts in the lower part of the ſtamens, on the inſide, being thickly clothed with hairs, whereas in *O. major* it is always perfectly ſmooth. The ſtigma of this is brown or purpliſh; that of *O. major* is yellow.

This has been ſo generally confounded with our *O. major* by foreigners, that it is impoſſible to allot to

[s] Linn. tranſ. 174-175. [t] Idem. 164.
[u] Sutton in Linn. tranſ. Curtis Lond. Woodw. Mſs. Reli. cant.
[x] Sutton in Linn. tranſ. [y] Pollich.

each

each its proper ſynonyms, no botaniſt having properly deſcribed the ſtamens, in which the true character reſides; much leſs do the figures of old authors lend any aſſiſtance towards this diſcrimination. The *caryophyllacea* is ſo named from its having a very ſtrong and fragrant ſmell of Cloves when freſh; whereas our plant has not the leaſt degree of that ſmell, though ſome Engliſh writers affirm that it has a faint ſmell of Cloves.

It was gathered by Dr. Smith on ſhrubby hills near Valcimara at the foot of the Apennines, in april 1787. Linnæus received it from Siberia[a]. Pollich found it about Lautereen in the Palatinate, in dry paſtures, orchards, corn-fields, and among hemp; flowering in may and june. Probably in other parts of Europe, but not ſo common as the firſt ſpecies.

4. This has a taller and more ſlender ſtem than *O. major*, and is upon the whole leſs pubeſcent. The bractes are ſhorter than the flowers. Corolla the ſize of *O. major*, but the upper lip is of a dark or purpliſh colour, and leſs fimbriated or criſped. The lower lip is remarkably ſhort, in three obcordate fimbriated ſegments, of which the middle one is larger than the other two, and is connected at its baſe with the very prominent two-lobed palate of the flower. The ſtamens are ſlender, thinly clothed all over, as well as the ſtyle, with ſcattered hairs, and project out of the mouth of the flower. The germ is ſmooth.

O. graciliſ has moſt affinity to the *minor* in ſome of its characters, but differs in its larger inflated corolla, ſhort lower lip, longer ſtamens and hairy ſtyle.

Gathered by Dr. Smith in hilly paſtures at St. Orſeſe near Genoa, in july 1787[b].

5. Root like thoſe of *O. major* and *elatior*, only with fewer ſcales, adhering for the moſt part to the woody root of *Trifolium pratenſe*. Stem from ſix to twelve inches high, erect, roundiſh, hairy, almoſt the thickneſs of a gooſe quill, fleſh-coloured, or ſometimes yellow, ſcaly but with fewer ſcales: there are ſeveral of them ſometimes aggregate. Flowers in ſpikes, whitiſh yellow with purple veins, hairy; varying of a full yellow; finally becoming rigid, and ferruginous: the lower flower is often pedunculed. Bractes ſimple, lanceolate, hairy, almoſt the length of the flowers. Calyx almoſt equal, of the ſame colour with the ſtem, hairy, two-leaved, lateral, with the leaflets ſometimes bifid; the ſegments very narrow, unequal; ſometimes ſimple, lanceolate, entire, or gaſhed on one ſide. Corolla four-cleft, hairy: tube cylindrical, ſpreading, incurved, keeled at the back: mouth open: border two-lipped, unequal; upper lip rounded, crenulate, entire; lower trifid; the ſegments equal, rounded, crenulate; varying ſometimes with the middle ſegment three-lobed. Nectary four ſaffron-coloured glands at the baſe of the filaments; which are ſmooth and naked in front, hairy behind, the hairs not glanduliferous; the two ſhorter inſerted into the ſides, the two longer into the anterior part of the tube. Anthers twin, mucronate at one of the tips; finally ſtanding out together with the ſtyle. Germ ovate-oblong, naked; ſtyle filiform, almoſt naked; ſtigma retuſe, dilated at the edge, purple, with a tranſverſe cleft along the middle; ſometimes it becomes triangular or ſquare. Capſule as in the others. Seeds wrinkled or obſoletely netted. It differs from *elatior* in its two-leaved variable calyx; from *major* in its cylindrical corolla; from both, in the ſmallneſs of the corolla.

It is frequently found with a much longer ſpike than it is repreſented with in Engliſh Botany; in which caſe the flowers are not only more numerous, but much cloſer ſet than in that figure. From its growing ſo very copiouſly among Clover it is probably the ſame which Dr. Turner noticed as being ſo pernicious to it. Dr. Smith remarks that this is the only ſpecies growing in ſuch ſituations or in ſuch abundance as to be deemed a weed. None of the other old Herbaliſts have mentioned it, nor has it been introduced into any of our Britiſh Floras, if we except Hudſon, who is thought to have it in his firſt edition; but from his uncertainty reſpecting it afterwards, it ſhould ſeem he took it upon truſt from Dillenius, who, in his edition of Ray's ſynopſis, ſpeaks of its being found in a field of oats near Rocheſter.

It might poſſibly not be unknown to Ray: for having deſcribed *O. majore flore* of John Bauhin, he adds that *O. flore minore* of the ſame author differs ſo little from it, that he can ſcarcely believe it to be a diſtinct ſpecies[c]. There is little doubt of its being different from thoſe above deſcribed.

It is found in fields of Clover, but not the firſt year; alſo in paſtures with *Hypochœris radicata*. It is in the Linnæan herbarium under the name of *Orobanche major*, and was given to Linnæus by Loefling. July and auguſt are the months of its flowering[d].

Vahl has an *Orobanche* which he gathered in the fields about Tunis, eſpecially among Beans. Although it differs in ſize and colour from *O. major*, yet he does not diſtinguiſh it ſpecifically from that. He frequently found it without ſcent, which is alſo the caſe in *O. major*, the ſtamens are included, as in that, and the anthers are awned in ſeveral of the ſpecies. The ſtems are a foot high or more, the thickneſs of the little finger, and the whole plant is of a duſky purple colour[e].

Micheli, in a little treatiſe on this genus, publiſhed in the Italian language at Florence in 1723, enumerates many varieties, among which probably ſome of the above ſpecies may be found. Gmelin, in his Flora Sibirica, has alſo ſeveral varieties. Haller has a variety of his n. 295. which is probably a diſtinct ſpecies, or a variety of our O. caryophyllacea[f]. Theſe obſcure notices ſolicit farther enquiry.

6. Stems ſcarcely ſo thick as the human finger, a ſpan high, round, coloured, ſucculent, imbricated all over with ovate-lanceolate, ſeſſile, acuminate, erect, coloured, ſhrivelling leaves. Spike ſeſſile, terminating, the length of the ſtem, imbricate with the fructifications. Bractes ſolitary, lanceolate, almoſt the length of the corolla. Flowers ſubſeſſile. Calyx ventricoſe, with the margin entire. Corolla incurved, with the border narrower; upper lip longer, lower two-parted, erect. The whole plant with the fructification yellow.

Found in Carolina at the roots of trees and ſhrubs, by Dr. Garden. Linneus received one very like it from Siberia, ſcarcely to be diſtinguiſhed except in the bluntneſs of the leaves[g].

7. Native of Spain and Siberia[h].

8. This is of a red purple when freſh, but turns black in drying. The flowers are large.—It was found at the Cape of Good Hope by Thunberg[i].

9. Root as in the other ſpecies, with fibres embracing the roots of different herbs. Stem from ſix to ten inches high, erect, rigid, ſomewhat hairy, a little flexuoſe, angular, ſomewhat woody, of a yellow olive colour, the thickneſs of a gooſe or ſwan's quill; the ſcales on it ovate-lanceolate. Flowers in looſe bluntiſh ſpikes, violet with deeper-coloured veins, ſlightly hairy, like thoſe of *O. ramoſa* but larger; becoming finally twiſted, compreſſed, drooping, duſky; the lower flower is often pedunculed. Bractes ſcarcely equal to the calyx, the two lateral ones interior, linear-lanceolate, the middle one exterior, ovate-lanceolate, with ſhort hairs. Calyx of the ſame colour with the ſtem, the four ſegments equal, lanceolate, acuminate, hairy, with the rudiment of a fifth at the deeper poſterior inciſure; ſometimes, but ſeldom, it is five-cleft with the rudiment of a ſixth ſegment behind. Corolla hairy, twice as long as the calyx; tube round below, gradually widening upwards, compreſſed-triangular, ſharply keeled at the back, bluntly incurved in the middle; mouth gaping; border two-lipped, almoſt equal; upper lip bifid; the ſegments bluntiſh, reflex, toothletted, lower three-lobed, with the ſegments equal, ſharpiſh, palate ſilky, being covered with white hairs preſſed cloſe but not glanduliferous. Filaments filiform, naked, ſmooth, ſcarcely recurved, the two ſhorter inſerted into the ſides, the two longer

[a] Smith in Linn. tranſ. [b] Idem.

[c] Hiſt. 1227. [d] Sutton in Linn. tranſ. [e] Symb. 2. 70. [f] Smith in Linn. tranſ. 4. 170. 171. [g] Linn. mant. [h] Linn. ſpec. [i] Linn. ſuppl.

into the anterior part of the tube. Anthers whitiſh yellow, converging within the mouth, finally included. Germ ovate-oblong, naked, even: ſtyle filiform, incurved, ſomewhat hairy: ſtigma headed, white, two-fobed, without any cleft in it, cloſing the mouth. Capſule ovate-oblong, grooved along the middle, opening longitudinally. Seeds ſubturbinate, netted-cellular.

This and the next ſpecies differ from the five firſt in many reſpects: the upper lip of the corolla is divided, the ſhape of the flower is not cylindrical, the ſtamens are ſhort and filiform, the ſtigma has no apparent tranſverſe fiſſure, the calyx is tubular, the bractes are ternate, and the plants altogether leſs ſucculent, and perhaps leſs parafitic.

The ſtem in this ſpecies, though generally, is not always unbranched. The little that was known of it in England, till lately, was from Mr. Pitchford's ſpecimen found in 1779, at Northrepps, and from Mr. Lightfoot's, now in the poſſeſſion of the Queen. Being moſt allied to *ramoſa*, it was taken at firſt for a variety of that. In 1796 Mr. Scrimpſhire found ſeveral plants of it at Sheringham, and Mr. Sutton a few in the adjoining pariſh of Beeſton. It ſeems to be more generally found abroad, where it has uſually paſſed for *O. Lævis* of Linnæus. It grows among graſs in paſtures, and on the borders of fields [a], in Switzerland, Auſtria, Germany, and the South of France.

10. Root a ſolid bulb, elliptical, naked, or furniſhed with one or two ovate-lanceolate ſeſſile ſcales; and numerous ſhort thick fibres, affixed laterally, and intermixed with the ſlender fibres of the roots of Hemp or other annual plants, and ſometimes to thoſe of graſs. Stem a continuation of the bulb, nearly round, brown or dirty yellow, naked or furniſhed with very few ſcales, (from ſix to ten inches high, upright, ſomewhat flexuoſe, hairy, ſomewhat woody, yellow tinged with purple, the thickneſs nearly of a ſwan's quill.) Branches either immediately from the root or alternate on the ſtem, ſwelling at the baſe, nearly erect, ſimilar to the ſtem, with each a ſcale, as before deſcribed, at the baſe. Stem and branches terminated by a thick (ſharp) ſpike of ſeſſile flowers, each having an ovate-lanceolate ſomewhat carinated bracteal ſcale. (The bractes are by threes, as in the preceding, ſhort, ſcarcely equal to the calyx, membranaceous, ſoon becoming duſky, the two lateral ones interior, lanceolate, acuminate, the outer one ovate-lanceolate.) Calyx of four acute ſegments, of which the two outer are largeſt. Tube of the corolla bellying at the baſe and yellow; upper part and lips blueiſh purple, hairy on the outſide: upper lip roundiſh, bifid, lower broad, trifid, the middle ſegment largeſt, and with two yellowiſh prominencies at the mouth. Filaments within the tube, blueiſh with yellow anthers, nearly equal. Style ariſing from the oval germ, longer than the ſtamens, and bending towards them, blueiſh with a blunt ſtigma. Capſule oblong. The ſtem is ſometimes ſimple, though rarely without one or two lateral branches, and then almoſt without ſcales [b].

It is diſtinguiſhed from the preceding by its ſharp ſpikes, the few ſcales on the ſtem and branches, the calyxes and bractes being ſhorter by half than the corolla, the tube of which after flowering is globular at bottom [c].

Native of ſeveral parts of Europe, South of France, Switzerland, Germany, England. Near Beccles in Suffolk, by James Sherard, M. D. Iſle of Sheppey and near Feverſham and Rocheſter, in Kent, about Glaſtonbury, and in Devonſhire and Hampſhire, by Hudſon. In hemp-fields near Wiſbeach, by Relhan; and at Outwell, in Norfolk. Brome near Bungay in Suffolk, on the firſt of ſeptember 1784, by Mr. Woodward. Mr. Sutton remarks, that it was probably introduced into England with Hemp. Mr. Woodward found it on *Galeopſis Tetrahit*. Linnæus ſays it is found *in ſegetis*; Dr. Withering gives it to corn fields and dry paſtures. Mr. Sutton has not known it to be found in any other than a rich light moiſt ſoil, ſuch as Hemp generally grows in. He doubts whether *O. ramoſa* of Oſbeck be the ſame with ours.

11. Stem a ſpan high or more, the thickneſs of the little finger, ſmooth, covered with ſcattered ovate-lanceolate, ſmooth ſcales, the uppermoſt broader, ſometimes acuminate. Spike three inches long, thick. Flowers alternate, contiguous, imbricated. Bracte the length of the calyx, of the ſame ſtructure with the ſcales on the ſtem, under each flower; two linear, ſhorter at the baſe of the calyx. Calycine ſegments oblong, ſmooth, one-third of the length of the corolla; which is an inch and half long; the tube widening towards the border and curved; lobes of the border rounded and quite entire. Filaments ſhorter than the corolla, hirſute at the baſe. Anthers oblong, villoſe, terminated by a dagger point at the baſe. Germ oblong. Style the length of the filaments. Stigma large. It varies with blue and yellow corollas, and narrower bractes a little longer than the calyx.—Native of Arabia and Barbary [d].

12. From a thickiſh root compoſed of ſcales with fibres annexed ariſe ſeven or eight ſtalks, a palm and half or a long ſpan in height, ſlender, hard and woody, with ſharp and ſcarcely conſpicuous ſcales, one of which is placed as a bracte to each flower. Flowers oblong of an obſolete colour, covering the ſtem from the very root. Capſules ſmall, round, hard, on a very ſhort peduncle. Seeds round, pale yellow, very ſmall. Sent by Baniſter from Virginia [e].

13. Stem of a ſhining red. Flowers ſmall, conſiſting of ſix petals, five of which are red and the ſixth white, without any ſpots. Capſule yellow [f]. Linnæus remarks, that the ſheath is ſpathaceous; the flower pale blue and hanging down.—Native of Virginia, where it flowers in october.

There are many other North American Orobanches in the Supplement to Ray's hiſtory, found there by Dr. Krieg, Baniſter and Vernon.

14. Stems quite ſimple, ſtrict, round, with three lines, without any leaves, terminated by one flower. A ſpathe inveſts the flower.—Native of Malabar [g].

Nat. order of *Papilionaceæ* or *Leguminoſæ.*

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, blunt at the baſe: *mouth* oblique, five-toothed, very ſhort; the three lower toothlets ſharper; the two upper ſhorter, more deeply and bluntly divided: ſhrivelling.

COR. papilionaceous: *banner* obcordate, reflex at the tip and ſides, longer: *wings* two, oblong, almoſt the length of the banner, riſing, converging: *keel* manifeſtly bifid below, acuminate, riſing; with the edges converging, parallel, compreſſed; the bottom ventricoſe.

STAM. *Filaments* diadelphous (ſimple and nine-cleft), aſcending. *Anthers* roundiſh.

PIST. *Germ* cylindrical, compreſſed. *Style* filiform, bent upwards, erect. *Stigma* linear, pubeſcent on the inner ſide from the middle to the top.

PER. *Legume* round, long, acuminate and aſcending at the end, one-celled, two-valved.

SEEDS very many, roundiſh.

ESSENTIAL CHARACTER.

Cal. blunt at the baſe; the upper teeth deeper and ſhorter. *Style* linear.

Mill. dict. n. 10. *Houſt. Mſs.*

Leaves pinnate oblong-ovate ſilky underneath, ſtem erect tomentoſe, flowers in terminating ſpikes.

15. Orobus procumbens. *Procumbent Bitter-Vetch.*
Mill. dict. n. 11. *Houſt. Mſs.*

Leaves pinnate, outer leaflets larger tomentoſe, ſtem procumbent.

16. Orobus coccineus. *Scarlet Bitter-Vetch.*
Mill. dict. n. 12. *Houſt. Mſs.*

Leaves pinnate, leaflets linear villoſe, ſtem procumbent, flowers axillary and terminating.

DESCRIPTIONS, &c.

1. Root perennial. Stalks three or four, branching, about a foot high. Leaflets ſmooth, ſtiff, of a lucid green. Flowers in cloſe ſpikes on ſhort peduncles, from the axils of the leaves at the top of the ſtalks, where are generally three or four of theſe ſpikes ſtanding together. The corolla is of a fine blue colour. The flowers appear in june, and are ſucceeded by ſhort ſtattish pods, containing two or three ſeeds in each, which ripen in auguſt.

Native of Siberia. [Cultivated in 1759 by Mr. Miller[s].

2. Native of Thrace[t].

3. Root very thick, often tranſverſe, hard, with the fibres widely diffuſed. Stem a foot high and more, ſtraight, angular, ſtriated, ſmooth. Leaflets four or five pairs, entire, veined on both ſides, netted, ſmooth, whitiſh underneath, terminated by a briſtle: ſometimes there is an odd leaflet. Stipules ſemiſagittate, entire or obſcurely ſerrate with diſtant teeth, of the ſame colour with the leaves. Peduncles angular, ſtriated, ſmooth, naked, twice as long as the leaves. Flowers in looſe ſpikes, all directed the ſame way, twelve or more. Calyx five-cleft, the lower legment longer. Corolla pale yellow, with the ſtandard and keel of the ſame length. Legumes long, linear, ſmooth, compreſſed.

It differs from the next ſpecies in having a higher ſtem, leſs angular; wider leaflets, narrower ſtipules,

[s] Hort. kew. [t] Linn.

longer

longer peduncles: and larger flowers, in greater abundance, of a yellow colour [a].

According to Turra in *Linn. mant.* the ſtem is three feet high, ſimple or branched; leaves glaucous underneath. Stipules quite entire and ſemiſagittate, not roundiſh creſcent-ſhaped and toothed.—Gerard ſays that the ſtem is ſimple; Haller, that it is altogether branched; Villars, that it is ſimple or branched.

Haller deſcribes it as one of the handſomeſt of the papilionaceous tribe; the ſtem three feet high and more; ſtipules large, hooked downwards, ſerrate; leaves numerous, aſcending, ſmooth; flowering ſtems from all the axils, a long ſpan in length, bearing a looſe pendulous ſpike of ten flowers; calyx cylindrical, compreſſed, the two upper ſegments very ſhort, lanceolate, recurved, the lower ſtraight and triangular; corolla long, ochroleucous; ſtandard narrow; wings blunt, equal to the keel, with blunt hooks; keel cloven at bottom, very ſharp at top; legume oblong, ſmooth, many-ſeeded.

Native of Siberia, Switzerland, the South of France and Italy. Cultivated in 1757 by Mr. Miller [b].

4. Root perennial, creeping, not tuberous, woody, black, with many ſtrong fibres. Stem about a foot high, upright, unbranched, ſmooth, angular, twiſted or elbowed at each inſertion of the leaves. Leaves alternate, petioled, leaflets two or three pairs, without an odd one, large, ovate-lanceolate, ſeſſile, quite entire, nerved, bright green, ſmooth, tender. Stipules at the baſe of the petioles, large, wide. Midrib or rachis of the leaf long, channelled, ending in a ſharp point. Peduncles axillary, an inch and half long, terminated by a one-ſided looſe raceme, conſiſting of from four to eight or ten flowers. The two upper toothlets of the calyx are ſhorter, the loweſt is longeſt. Corolla large and handſome, ſingular in the different ſhades of colour: the ſtandard is wide and emarginate, the upper part of it is red or purple with blood-red veins, the wings are blue, the keel is blue tinged with green; the colours change as the corolla advances, and become ſky-blue when the corolla is ready to fall. Legumes ſtraight, round, from red becoming black, and containing from five or ſix to nine or ten rounded, compreſſed ſeeds [c].

Scopoli remarks, that the pedicels are ſhorter than the calyx; that the uppermoſt ſtamen is bowed, and applies its anther to the baſe of the ſtigma, and that all the filaments are not antheriferous.

Native of many parts of Europe, in woods. Cultivated here in 1629, as appears from Parkinſon [d]. It flowers early, namely in march or april, or, as Scopoli expreſſes it, before the arrival of the Swallow.]

Mr. Miller mentions a variety of it with pale flowers:

5. [Root perennial, conſiſting of tough fibres, ſwelling here and there into irregular tubercles, each of which produces a ſtalk about a foot high, ſimple, upright, having two or three leafy or winged angles. Leaves alternate, three or four in number; each conſiſting of two or three pairs of ſmooth ſeſſile leaflets without an odd one, the petiole terminated by a kind of awn, as are the leaflets, being a production of the midrib; leaflets all elliptical, blueiſh underneath, the lower ones broader, the upper approaching to linear, all having three nerves or longitudinal veins. Stipules in pairs at the baſe of each leaf, frequently entire, but more often jagged at bottom, with one or ſeveral teeth. Flowers from two to four or five in a thin ſpike on naked ſlender axillary peduncles. Calyx purple, blunt at the baſe, the three loweſt teeth ſharper, the two upper ſhorter. Corolla beautiful, reddiſh purple, turning blue as it goes off: ſtandard large, oval, veined, with reflexed elevated margins; wings converging, connected with the keel, claw linear; keel acuminate, riſing upward, with hollow edges for the reception of the wings. At the baſe of the uppermoſt or ſingle filament two ſmall holes are conſpicuous. Germ a flatted cylinder: ſtyle interiorly near the top villoſe, not pointed at the end. Legume above an inch long, cylindrical, a little curved at the end, firſt red, but black when ripe, pendent, containing from four to nine or even twelve roundiſh compreſſed ſeeds of a yellowiſh brown colour [e].

Native of moſt parts of Europe, in woods, principally in a ſtrong clayey ſoil; flowering in may and june, ſometimes in april: the ſeed is ripe in july. The root is large, deep in the earth, and taken up with difficulty. The Highlanders of Scotland have a great eſteem for the tubercles of the root; they dry and chew them in general to give a better reliſh to their liquor; they alſo affirm them to be good againſt moſt diſorders of the thorax, and that by the uſe of them they are enabled to repel hunger and thirſt for a long time. In Breadalbine and Roſsſhire they ſometimes bruiſe and ſteep them in water, and make an agreeable fermented liquor with them. They have a ſweet taſte, ſomething like the roots of liquorice, and when boiled, are well-flavoured and nutritive, and in times of ſcarcity have ſerved as a ſubſtitute for bread [f].

In Engliſh it is called *Wood-Pea* or *Heath-Pea*. Dr. Withering names it *Heath-Perſeling*. In Erſe it is *Cor-meille*.

Retzius mentions a variety, with the ſtem more than a foot high, wide large ovate blunt leaves, and great ſtipules croſe-toothed at the baſe.

6. This has the habit of the preceding, but the leaves are enſiform-lanceolate with two or three pairs of oppoſite leaflets without any tendril. Flowers few, yellow, in racemes [g].

Native of Siberia. Cultivated in 1766, in the Botanic Garden at Oxford [h].

7. Roots tuberous, ſeſſile. It reſembles the preceding very much, but the leaves are petioled and not ſubſeſſile; the flowers are white, not yellow; racemes without any terminating thread. Native of Auſtria [i].

8. This alſo reſembles O. anguſtifolius, but the ſtem is branched, and the flowers are white with a tinge of blue [k].

It differs from O. anguſtifolius in having a branched ſtem, and blue flowers; nor is it a native of the Alps; but of the Levant, and the South of France, in barren paſtures.]

9. Root perennial, ſtrong, woody. Stems many, branching, two feet high, having one pinnate leaf at each joint, compoſed of five or ſix ſmall, oblong, oval leaflets. Flowers on very long, axillary peduncles, having four, five or ſix purple flowers at the top.

[Stem upright, a foot and half high, with alternate branches. Leaflets five or ſix pairs, hardiſh, glaucous-green, ovate, acuminate, the midrib ending in a point. Stipules pale, lanceolate, terminating in little hooks at the baſe. Peduncles axillary, three inches long, bearing ſix or ſeven (ſometimes twelve) flowers in a raceme, often pointing moſtly one way, hanging down. Corolla purple, eaſily changing colour: ſtandard emarginate, bent back; wings ending in blunt hooks, extending a little beyond the keel, which ends in a ſharp beak. Stigma bent down [l]. Legume two inches long and more, about a line and half wide, at firſt pendulous, but extending more ſtraight out as it ripens, oblong, roundiſh, incurved a little at the baſe, ending in a point, knobbed a little where the ſeeds lie, ſmooth, black. Seeds from three or four to ſix or eight, orbicular, cylindrical or conoid-ovate, ſmooth, with ſmall, ſcattered, duſky ſpots: navel linear, almoſt the length of the ſeed, chord very ſhort, biſid at top [m].

Native of moſt parts of Europe, in woods and among buſhes, but not of Britain, flowering from may to july.—Cultivated in 1656, by Mr. John Tradeſcant junior [n]. It turns black in drying, whence the trivial name.

10. Stem angular, with the angles ſlightly winged, branched, ſomewhat villoſe. Leaflets on ſhort petioles, the nerves underneath villoſe. Stipules oblong,

[a] Gerard. [b] Hort. kew. [c] Haller, Pollich, Villars, Krocker. [d] Hort. kew. [e] Lightf. Curtis, Woodw. Mſs. Withering. [f] Lightfoot. [g] Linn. ſpec. [h] Hort. kew. [i] Linn. ſuppl. [k] Idem. [l] Pollich, Scopoli. [m] Gærtner, Pollich. [n] Hort. kew.

one

one-tailed. Racemes ſcattered. Flowers directed one way, pendulous: ſtandard obcordate, red, with lines of a deeper colour. Legume ſubpubeſcent[a].

Native of the South of Europe.—Cultivated in 1699, by the Dutcheſs of Beaufort[b].

11. From the root ariſe numerous procumbent ſtems, much branched, and even the younger ſhoots but ſlightly hairy. Leaves alternate, with each a pair of ſemiſagittate ſtipules at the baſe, reſembling thoſe of O. tuberoſus, but ſmaller, and terminating in a more acute point. Leaflets oval or elliptical, never acutely pointed, terminated by the produced midrib, as in O. tuberoſus, on very ſhort hairy footſtalks, ſomewhat alternate, ſix to twelve pairs without an odd one, but a ſort of beard terminating the footſtalk, which as well as the ſtem is but ſlightly hairy. The flowers numerous to twelve, on ſhort pedicels, crowded on the ſummit of a long naked peduncle, moſtly pointing one way. Calyx ſhort, ſomewhat bilabiated, nearly equal, the upper lip conſiſting of two teeth, the lower of three rather longer, green tinged with red, and fringed with hairs. Coroſla long and narrow. Legume ſhort, compreſſed, ſmooth[c].

According to Linnæus, the ſtems are branched and grooved, leaflets ſix or ſeven pairs, coroſla red on the outſide, white within with purple lines, legume compreſſed containing two or three ſeeds.

Lightfoot deſcribes the flowers as white ſtriated with purple veins, the apex of the keel bright purple. Legumes hardly an inch long. The whole plant has a diſagreeable bitter taſte.

Mr. Woodward remarks, that his ſpecimens differ ſo materially in ſome points from Mr. Lightfoot's deſcription and figure, that he ſhould have been tempted to ſuppoſe his a different plant, were it not that he gathered it on the ſpot deſcribed by Ray, and that it anſwers to the deſcription in the ſynopſis, which is quoted by Linnæus; and is as follows.

Root thick, woody, perennial, with a leguminous taſte. Stems numerous, a foot or eighteen inches in height, hairy, ſtriated, branched, reclining, although they are rigid. Leaves ſmaller than thoſe of the common Vetch, to ſeven or eight pairs, without any odd leaflet or tendril, dark green above, ſmooth beneath. Flowers ſix, ſeven or more on the ſame common peduncle, approaching in their form to thoſe of *Vicia ſylveſtris multiflora* or *Glycyrrhiza ſylveſtris*, pendulous on ſlender pedicels, reddiſh on the outſide, white with purple veins within. Legumes ſhort, broad, ſmooth, containing two or three, ſeldom more, ſmall, compreſſed, greeniſh ſeeds.

Native of France and England. Found by Mr. Ray at Gamblesby in Cumberland, about ſix (ten) miles from Penrith, in the way to Newcaſtle, in the hedges and paſtures plentifully: by Tho. Williſel below Brecknock-hills in the way to Caerdiff, and in Merionethſhire not far from Bala: in Denbighſhire by Mr. Griffith. In the upper part of Merley-wood near Oxford, by Dr. Sherard. In Scotland plentifully by Mr. Sutherland and Dr. Hope; on the Tweed half a mile below the Buld, by the latter; in the woods about Airly Caſtle, by Mr. Donn; on the bank of the Clyde near Lanerk, and in the iſle of Rum, by Mr. Lightfoot. In Ireland, near Roſs-Trevor, by Dr. Sherard. It flowers from may to july.]

12. Root perennial. Stalks two or three, about a foot high. Leaflets ſmooth, pale green, placed pretty far diſtant on the midrib. Peduncles axillary, ſlender, ſuſtaining four or five purple flowers at the top. Legumes ſwelling, an inch and half long, containing three or four roundiſh ſeeds. The flowers appear in march or april, and the ſeeds ſometimes ripen in may. Native of Italy.

13. This grows naturally in Jamaica, whence the late Dr. Houſtoun ſent the ſeeds in 1731. This riſes with a very branching woody ſtalk about three feet high; the leaves are compoſed of five or ſix pairs of narrow ſpear-ſhaped leaflets, which are woolly on their under ſide. The flowers grow in looſe ſpikes at the end of the branches, are of a pale purple colour, and are ſucceeded by ſmooth compreſſed pods an inch and a half long, each containing five or ſix roundiſh ſeeds.

14. The fourteenth ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz, whence he ſent the ſeeds to England. This riſes with a ſhrubby ſtalk five or ſix feet high, dividing into many ſlender branches, which are covered with a brown woolly bark, and have ſoft, fatteny, winged leaves; thoſe on the young branches are compoſed of four pairs of oval obtuſe leaflets, of a browniſh green colour, hairy on their upper ſide, but of a ſilvery ſilky hue on their under. The leaves on the upper branches are compoſed of ſeven or eight pairs of oblong oval leaflets, of the ſame colour and conſiſtence as the lower. The flowers are produced in long erect ſpikes at the end of the branches; they are of a deep purple colour, and are ſucceeded by long, woolly, compreſſed pods, each containing four or five ſeeds.

15. The fifteenth ſort was diſcovered by Dr. Houſtoun at La Vera Cruz, and he ſent it to England in 1730. This is a low plant, whoſe ſtalks bend to the ground, and are ſeldom more than ſix or eight inches long, from which come out a few ſhort ſide branches; the leaves are compoſed of four or five pairs of ſmall, oblong, oval, woolly leaflets, terminated by an odd one, the upper ones being much larger than the lower. The flowers come out in ſmall bunches, ſtanding upon ſhort axillary peduncles; they are ſmall, and of a bright purple colour; theſe are ſucceeded by compreſſed pods near two inches long, each having ſix or ſeven roundiſh compreſſed ſeeds.

16. This was diſcovered at the ſame time, growing naturally in the ſame country as the former, by the ſame gentleman. It has a pretty thick woody root, which ſends out many ſlender ſtalks a foot and half long, trailing upon the ground; leaves compoſed of three or four pairs of narrow hoary leaflets, about half an inch long. The flowers come out from the ſide and at the end of the ſtalks, three or four ſtanding upon a ſhort footſtalk; they are ſmall and of a ſcarlet colour, and are ſucceeded by ſhort taper pods, each containing three or four ſmall roundiſh ſeeds.

PROPAGATION AND CULTURE.

All the ſpecies, except the four laſt, are hardy perennials, and ſeveral of them may be increaſed by parting their roots. The beſt time for doing this is in the autumn, that the plants may be well eſtabliſhed before the ſpring; for as ſeveral of them begin to put out their ſtalks very early in the ſpring, ſo if they are then diſturbed, it will either prevent their flowering, or cauſe their flowers to be very weak. Moſt of theſe plants delight in a ſhady ſituation, and a loamy ſoil.

They are alſo propagated by ſeeds, but theſe ſhould be ſown in the autumn, for if they are kept out of the ground till ſpring, many of the ſorts will never grow, and thoſe which do, ſeldom vegetate the ſame year. When the plants come up they muſt be kept clean from weeds, and where they are too cloſe together they ſhould be thinned, ſo as they may have room to grow till the autumn, when they ſhould be tranſplanted into the places where they are deſigned to remain. If the roots are ſtrong, they will flower very well the following ſpring, but thoſe which are weak will not flower till the ſecond year; therefore ſuch may be planted in a ſhady border at four or five inches diſtance, where they may grow one year to get ſtrength, and then may be removed to the places where they are to remain. The farther care of them is only to dig the ground between them in winter, and in ſummer to keep them clean from weeds.

The four laſt mentioned ſorts being natives of hot countries are tender, and muſt be preſerved in ſtoves, otherwiſe they will not live in England. Theſe are propagated by ſeeds, which ſhould be ſown early in the ſpring, in ſmall pots filled with light rich earth, and plunged into a hot-bed of tanner's bark, obſerving frequently to moiſten the earth, otherwiſe the ſeeds will not grow. When the plants come up, they ſhould be carefully taken out of the pots, and each tranſplanted

[a] Scopoli. [b] Hort. kew. [c] Woodw. Mſs.

transplanted into separate small pots filled with rich earth, and then plunged again into the tan-bed, observing to shade them until they have taken root: after which time they should have fresh air admitted to them every day in warm weather, and must be frequently watered. With this management the plants will make a great progress. When any of the plants are grown too tall to remain in the hot-bed, they should be taken out, and plunged into the bark-bed in the stove, where they may have room to grow, especially the thirteenth and fourteenth sorts; but the other two being of humbler growth, may be kept in the hot-bed until Michaelmas, when the nights begin to be cold; at which time they should be removed into the stove, and plunged into the bark-bed, where they must be treated as other tender exotic plants; by which method they may be preserved through the winter, and the following summer they will produce flowers. These plants are perennial, so that if they should not perfect their seeds, the plants may be maintained for several years.

DESCRIPTIONS, *&c.*

1. The leaves of this are broad, like those of Lily of the Valley, green on the upper side, and covered with very minute hairs, so that they look like a fine velvet. Cattle, hogs and stags are very fond of these leaves in the spring, and they come out among the earliest. The Indians gather the seeds and eat them when dried like peas; boiling them repeatedly in water before they are fit for use: they also boil them in milk or butter, and use them instead of bread. They call the plant *Taw-kee*. It grows in marshes, near moist and low grounds very plentifully in Virginia, Canada and other provinces of North America[a]. It was introduced here in 1775, by John Fothergill, M. D. and flowers in june[b].

2. Radical leaf solitary, ensiform, attenuated at bottom, convoluted, having several longitudinal veins, entire, smooth, two inches wide, and two feet long. Scape round, smooth, upright, from a finger to a palm in height. Flowers at the top of the scape distinct, in an oblong spike, an inch in length. It differs from the preceding in having much longer leaves attenuated below and marked with several raised veins, and a shorter scape.

Native of Japan, near Nagasaki, &c.[b] Introduced in 1783 by Mr. John Græfer. It flowers in january[c].

DESCRIPTIONS, *&c.*

1. Root round, knobbed, descending, with branched fibres in the lower part. Stems several, a foot high, thickened at the joints, which are red, and distant; branches from bottom to top, decussately opposite, erect, subdivided. Leaves almost linear, opposite, sessile, erect, bright green, as is the whole plant. Between each pair of leaves are two red tubercles on each side, from the centre of which issues a bristle-shaped, whitish, deciduous stipule. Flowers herbaceous, small, from each axil, and frequently a third from the forking of the branchlets, so close as to appear to be glomerate, on very short peduncles. Calycine leaflets ovate-acute, concave, two exterior, three interior. Filaments inserted into the base of the germ, yellowish, concealed within the internal leaflets of the calyx: anthers cordate at the base, acute at the tip. Germ superior, acute at both ends, ventricose, sharpest at the tip: style erect: stigma red. Seeds ovate, yellowish red.

It is a low trailing annual plant, native of Spain, where it was first observed by Clusius[d]. Cultivated in 1768, by Mr. Miller. It flowers in june and july[e]. In the Kew catalogue it is marked as perennial.—Gærtner remarks, that the embryo is straight, which is unusual in this family.

2. Root perennial. Stature of Galium. Stem erect, stiff, somewhat rugged, channelled on each side, thickened at the joints. Leaves opposite, linear, spreading, by no means smooth at the back. Two stipules on each side between each pair of leaves, minute bristle-shaped, with a thickish coloured base. Branches alternate. Panicle terminating. Flowers dichotomous on very short peduncles, green. Stigmas three, distinct, oblong, pubescent, each thicker than the style. It is very nearly allied to Polycarpon[f].—Native of Italy. Introduced in 1781, by Mons. Thouin. It flowers in august and september[g].

DESCRIPTION, *&c.*

Rice has the culm from one to ſix feet in length, annual, erect, ſimple, round, jointed. Leaves ſubulate-linear, reflex, embracing, not fleſhy. Flowers in a terminating panicle. Calycine leaflets lanceolate. Valves of the corolla equal in length; the inner valve even, awnleſs; the outer twice as wide, four-grooved, hiſpid, awned. Style ſingle, two-parted.

α. Culm four feet high. Panicle ſpiked, the ſpikes commonly ſimple. Fruit oblong, pale, with long awns. It is late, and is cut from ſix to eight months after planting. Cultivated in marſhes, and withering with drought or a ſmall degree of ſaltneſs.

β. Culm three feet high. Panicle ſpiked; ſpikes branching. Fruit turgid, browniſh red, with ſhorter awns. It ripens and is cut in the fourth month from planting. It is cultivated in marſhes, and is not injured by the influx of ſalt water.

γ. Culm three feet high, and more ſlender. Fruit longiſh, with awns the longeſt of all. It is ſown on mountains, and in dry ſoils; rots with a long inundation, and periſhes with ſea water.

δ. Culm four feet high. Leaves wider, yelloviſh. Panicle large, with ſhorter awns. Seed oblong, largiſh, glutinous, uſually very white. This is cultivated both in wet and dry places. It varies with a black ſeed, which is higher flavoured, and alſo with a red ſeed[k].

The varieties of Rice, as of other cultivated grain, are innumerable. Loureiro propoſes the above as ſpecies, diſtinct not from culture, but by nature; differing in the time of ſpringing, growth and maturity, in the ſort of ſoil that they require, in the form and colour of the ſeed, and probably in other characters, if they were carefully examined.

[k] Loureiro.

The native place of Rice, like the other ſorts of grain in common uſe, is unknown. Linnæus indeed ſays, *habitat ſorte in Æthiopia*, but I do not know what authority he has for this aſſertion. By a miſtake he has generally put Æthiopia for the country about the Cape of Good Hope: but perhaps he may here intend Abyſſinia.

Rice is cultivated in great abundance all over India, where the country will admit of being flooded; in the ſouthern provinces of China; in Cochinchina, Cambodia, Siam, Japan, &c. In Japan it is very white and of the beſt quality.

It has alſo been introduced into cultivation in the ſouthern kingdoms of Europe, Italy, Spain, the South of France, and within a few years into Hungary.

In Carolina it has long been a ſtaple commodity. Mr. Houghton's account of its introduction there is, that Mr. Aſhby was encouraged to ſend a hundred pound bag full of Rice to that province, from which in 1698, ſixty tons were imported into England[l].

Mr. Dalrymple ſays, that Rice in Carolina is the reſult of a ſmall bag of Paddy, given as a preſent from Mr. Dubois treaſurer of the Eaſt India Company to a Carolina trader. A Dutch veſſel alſo from Madagaſcar brought Rice into the ſame province; and to this is attributed their having two kinds[k].

Mr. Miller cultivated it here in 1739[l]: but Gerarde had it long before, for he ſays "the flower did not "ſhow itſelf with me, by reaſon of the injury of our "unſeaſonable year 1596." In his time ſtoves were unknown.

In the hilly parts of Java, and in many of the Eaſtern Iſlands, the Mountain Rice is planted upon the ſides of hills, where no water but rain can come; it is however planted in the beginning of the rainy ſeaſon, and reaped in the beginning of the dry ſeaſon. The natives call it *Paddy Gunung*, which ſignifies Mountain Rice. In the weſtern parts of India it is entirely unknown[m].

It is well known in Cochinchina, where it thrives in dry light ſoils moſtly on the ſides of hills, not requiring more moiſture than the uſual rains and dews ſupply, neither of which is frequent at the ſeaſon of its vegetation[n].

The French colonies are indebted to M. Poivre for introducing this dry rice in Cochinchina[o].

PROPAGATION AND CULTURE.

In China.

Much of the low grounds in the middle and ſouthern provinces of China is appropriated to the culture of Rice; which conſtitutes the principal part of the food of all thoſe who are not ſo indigent as to be forced to ſubſiſt on cheaper kinds of grain. A great proportion of the ſurface of the country is well adapted to the production of Rice. Many and great rivers run through the ſeveral provinces of China; the low grounds bordering on thoſe rivers are annually inundated, by which means a rich mud or mucilage is brought upon their ſurface, that fertilizes the ſoil, in the ſame manner as Egypt is by the overflowing of the Nile.

After the mud has lain ſome days, preparations are made for planting Rice. For this purpoſe, a ſmall ſpot of ground is incloſed by a bank of clay; the earth is ploughed up; and an upright harrow with a row of wooden pins in the lower end, is drawn lightly over it by a buffalo. The grain, previouſly ſteeped in dung diluted with animal water, is then ſown very thickly on it. A thin ſheet of water is immediately brought over it, either by channels leading to the ſpot from a ſource above it, or when below it, by means of a chain-pump, the uſe of which is as familiar as that of a hoe to every Chineſe huſbandman. In a few days the ſhoots appear above the water. In that interval, the remainder of the ground intended for cultivation, if ſtiff, is ploughed, the lumps broken by

[o] Rochon, Madag. introd. p. 45.

hoes,

hoes, and the ſurface levelled by the harrow. As ſoon as the ſhoots have attained the height of ſix or ſeven inches, they are plucked up by the roots, the tops of the blades cut off, and each root is planted ſeparately, ſometimes in ſmall furrows turned with the plough, and ſometimes in holes made in rows by a drilling ſtick for that purpoſe. The roots are about a foot aſunder. Water is brought over them a ſecond time, for the convenience of irrigation, and to regulate its proportion. The Rice fields are ſubdivided by narrow ridges of clay into ſmall incloſures. Through a channel in each ridge the water is conveyed at will to every ſubdiviſion. As the Rice approaches to maturity, the water, by evaporation and abſorption, diſappears entirely; and the crop, when ripe, covers dry ground. The firſt harveſt, in the ſouthern provinces particularly, happens towards the end of may or beginning of june.

The inſtrument for reaping is a ſmall toothed ſickle. The ſheaves are placed regularly in frames, two of which ſuſpended at the extremities of a bamboo pole are carried acroſs the ſhoulders of a man to the place where it is to be threſhed. This operation is performed not only by a flail, or by the treading of cattle, but ſometimes alſo by ſtriking it againſt a plank ſet upon its edge, or by beating it againſt the ſide of a large tub ſcolloped for that purpoſe; the back and ſides being much higher than the front, to prevent the grain from being diſperſed. After being winnowed it is carried to the granary.

To remove the ſkin or huſk of Rice, a large ſtrong earthen veſſel, or hollow ſtone, in form ſomewhat like that which is uſed elſewhere for filtering water, is fixed firmly in the ground, and the grain, placed in it, is ſtruck with a conical ſtone fixed to the extremity of a lever, and cleared, ſometimes indeed imperfectly, from the huſk. The ſame object is attained by paſſing the grain between two flat ſtones of a circular form, the upper of which turns round upon the other, but at ſuch a diſtance from it as not to break the grain. The operation is performed on a larger ſcale, in mills turned by water; the axis of the wheel carrying ſeveral arms, which raiſe levers by ſtriking upon the ends of them. Sometimes twenty of theſe levers are worked at once. The ſtraw is cut chiefly into chaff, to ſerve as provender for the very few cattle employed in Chineſe huſbandry.

The labour of the firſt crop being finiſhed, the ground is immediately prepared for the reception of freſh ſeeds. The firſt operation is to pull up the ſtubble, collect it into ſmall heaps, burn it, and ſcatter the aſhes upon the field. The former proceſſes are afterwards renewed. The ſecond crop is generally ripe late in october or early in november. The grain is treated as before; but the ſtubble is no longer burnt. It is turned under with the plough and left to putrefy in the earth. This, with the ſlime brought upon the ground by inundation, are the only manures uſually employed in the culture of Rice. Lands thus fertilized by the overflowing of the tide in the proximity of the ſea, or of rivers or canals, are not appropriated ſolely to the production of Rice. They are found equally ſuitable for raiſing an excellent crop of ſugar canes, with the precaution only of keeping off the water after the young canes appear above the ſurface.

Satisfied with two crops of Rice or one of Sugar in the year, the Chineſe huſbandman generally ſuffers the land to remain at reſt till the following ſpring, when the ſame proceſs is repeated. And thus from generation to generation, ſucceſſive crops are raiſed from the ſame ſoil, without the leaſt idea of any neceſſity to let the earth lie fallow or idle for a year*.]

Culture in England.

Sow the ſeeds on a hot-bed, and when the plants are come up, tranſplant them into pots filled with rich light earth, and placed in pans of water, which ſhould be plunged into a hot-bed; and as the water waſtes it muſt be renewed from time to time. Keep them in the ſtove all the ſummer, and towards the end of auguſt, they will produce the grain, which will ripen tolerably well, provided the autumn prove favourable.

[ORYZA. See *Paſpalum.*

OSBECKIA. (*So named by Linnæus, in honour of Peter Oſbeck, rector of Haſſelef and Wexiorp in Sweden, member of the academy of Stockholm, and of the ſociety of Upſal: author of a Voyage to China and the Eaſt Indies, in* 1751; *printed in* 1757—*Engliſh by Forſter*, 1771.)

Lin. gen. n. 467. *Reich. n.* 503. *Schreb. n.* 635. *Gærtn. t.* 126. *Juſſ.* 330.

Claſſ. 8. 1. Octandria Monogynia.

Nat. order of *Calycanthemæ. Melaſtomæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-ſhaped, permanent: *border* four-parted, deciduous: *lobes* oblong, acute, with a ciliate ſcalelet interpoſed between the lobes.

COR. *Petals* four, roundiſh, ſeſſile, longer than the calyx.

STAM. *Filaments* eight, filiform, ſhort. *Anthers* oblong, erect, terminated by a filiform beak, the length of the anther itſelf.

PIST. *Germ* inferior, ovate, faſtened to the calyx below, terminated at top by four ciliate ſcales. *Style* awl-ſhaped, the length of the ſtamens. *Stigma* ſimple.

PER. *Capſule* clothed with the truncated tube of the calyx, ſubovate, four-celled, the cells gaping longitudinally at the top.

SEEDS very many, roundiſh. *Receptacles* creſcent-ſhaped, (wide, compreſſed, *G.*)

ESSENTIAL CHARACTER.

Cal. four-cleft, with the lobes ſeparated by a ciliary ſcale (or five-cleft without intercalated ſcales, *G.*) *Cor.* four-petalled (or five-petalled. *Stam.* eight or ten. *G.*) *Anthers* beaked. *Capſ.* inferior, four-celled (or five-celled, *G.*) ſurrounded by the truncated tube of the calyx.

SPECIES.

1. Oſbeckia chinenſis.

Leaves ſeſſile, peduncles axillary three-flowered bracted.

2. Oſbeckia zeylanica.

Lin. ſyſt. 357. *ſuppl.* 215.

Leaves petioled, peduncles axillary one-flowered naked.

DESCRIPTIONS, *&c.*

1. Root perennial, woody, ſometimes conſiſting of a little knob with branches. Stems quadrangular, the thickneſs of a packthread, ſeldom exceeding half a yard in length, generally branched, and ſometimes like a little buſh. The branches, which are quadrangular and ſomewhat hairy, are commonly oppoſite, and ſingle, or not divided. On the top are commonly two flowers, ſurrounded with four leaves, two of which are ſhort, but longer than the flowers: the leaves are oppoſite; each couple is an inch or more from the other, and the nearer to the flower the farther they are aſunder. They are ſomewhat obtuſe in young plants, and about an inch long, but in old ones they are longer, and ſharp: thoſe which grow at the bottom of the branches are frequently as long again as the others. Moſt of them have no petiole, and are lanceolated ſometimes, yet narrower; almoſt every where of equal breadth; margins entire; the upper ſide covered with ſtiff hairs which lie down; on the under ſide, on the edge, and upon the three veins, which run almoſt the whole length of the leaf in a ſtraight line, there is only a thin pubeſcence. The calycine ſegments are ſomewhat downy on the outſide. Petals red. Filaments inflected, and together with the petals, faſtened to the calyx: of the ſame length with the calyx, and conſequently ſhorter than the petals. The capſule looks like a little pot or pitcher, running narrower to the bottom. Seeds ſmall, in a microſcope looking like little worms lying in a circular form†.

According to Linnæus it has the habit of Melaſtoma. Stem erect, brachiate, acutely quadrangular. Leaves

* Staunton, Emb. to China, 2. 392 to 397. See Thunberg's travels, 4. 85. 3. 148.

† Oſbeck.

narrow-

narrow-lanceolate, three-nerved, oppoſite, rugged, ſubſeſſile. Flowers terminating, few, ſeſſile, ſurrounded by four leaves, longer than the flower, and ſpreading [1].

Loureiro ſays that the ſtem is two feet high, ſuffruticoſe, hairy, branched. Leaves hiſpid, quite entire. Flowers red, heaped, terminating, pedunculed. Anthers oblong, tailed, not broken, nor beaked. Berry roundiſh, juiceleſs.

According to Gærtner, the ſeed-veſſel is an inferior ovate Capſule, covered with the hiſpid calyx adhering cloſe to it, and with ſtiff cluſtered briſtles, ſcarcely conſtituent into ſcales, crowned at the top, five-celled, and opening into five parts above. Receptacles five, one in each cell, ſemiovate, wedge-form-compreſſed, free on one ſide, on the other faſtened longitudinally to the axis of the capſule. Seeds very numerous, ſmall, globular-kidney-form, ſomewhat ruſſet, or dirty ſtraw-coloured. Skin double: outer cruſtaceous, brittle; inner membranaceous, very thin: no veſtige of any albumen: embryo of the ſame ſhape with the ſeed, bowed, yellow; cotyledons plano-convex, ſhort, thick; radicle longer than the cotyledons, curved centripetal. Gærtner doubts, whether the fruit here deſcribed, may not rather be that of Oſb. zeylanica.

Native of the Eaſt Indies and China. The Chineſe call it *Komm-Heyong-hoaa*, or *Feather of Gold Roſes*. The whole plant is ſold in the apothecaries ſhops; they boil it with old *Kuii-Tea*, and drink the decoction in colics. In ſtrains and ſwellings it is uſed in the bath [2].

2. In appearance this reſembles the preceding very much. It is a native of Ceylon, and was found there by Koenig [3].

OSIER. See *Salix*.

OSMANTHUS. See *Olea*.

OSMITES. (*From* Ὀσμὴ, *odor: on account of its powerful ſweet ſmell.*)

Lin. gen. n. 983. *Reich. n.* 1063. *Schreb. n.* 1326. *Gærtn. t.* 174. *Juſſ.* 186. Bellidiaſtrum. *Vaill. mem. par.* 1720.

Claſſ. 19. 3. Syngeneſia Polygamia Fruſtranea.

Nat. order of *Compoſitæ Diſcoideæ. Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* imbricate, gibbous; with the inmoſt leaflets augmented at the tip.

COR. *Compound* radiate: *Corollets* hermaphrodite ſeveral in the diſk. *Female* in the ray.

Proper of the hermaphrodite tubular, five-cleft: of the female ligulate, entire.

STAM. in the hermaphrodites, *Filaments* five, very ſhort. *Anther* cylindrical, tubular.

PIST. in the hermaphrodites: *germ* oblong; *ſtyle* filiform, the length of the corollet; *ſtigma* bifid. In the females, *germ* ſmaller; *ſtyle* filiform, the length of the corollet; *ſtigma* obſolete.

PER. none. *Calyx* unchanged.

SEEDS in the hermaphrodites ſolitary, oblong; with ſcarcely any *pappus*, or only margined: the *pappus* obſolete and ſomewhat chaffy:—in the females, rudiments commonly abortive.

RECEPT. chaffy.

ESSENTIAL CHARACTER.

Cal. imbricate, ſcarioſe. *Cor.* of the ray ligulate. *Down* obſolete. *Recept.* chaffy.

Leaves lanceolate dotted, ſtems leafy.

4. Oſmites calycina.
Lin. ſyſt. 783. *ſuppl.* 380.
Leaves lanceolate naked, calyxes ſcarioſe.

DESCRIPTIONS, &c.

1. Branches woody and thickiſh. Leaves oblong, narrow, acute, nearly of the ſame form and ſize with thoſe of Hyſſop, ſeſſile, all over the branches to the very flowers, which are ſeveral in number at the ends of the ſtem and branches: the diſk of them is yellow and the ray white [4].

2. Stems quite ſimple, with one pedunculed flower. Leaves like thoſe of *Coryſanthemum Leucanthemum*, or Ox-eye Daiſy, tooth-ſerrate, naked, gradually ſmaller towards the top: they are ſeſſile, alternate, cluſtered, tomentoſe. Ray of the corolla white; diſk yellow [5].

Receptacle ſomewhat convex: chaffs between the florets linear-oblong, concave, a little ſhorter than the calyx, or the ſame length with the florets of the diſk. Linnæus remarks that they are blueiſh at the tip. Seeds ſmall, ovate, attenuated each way to an obſolete edge, convex on one ſide and grooved or ſtriated, flat on the other; pale. *Pappus* chaffy, many-leaved; leaflets ſhorter by half than the ſeed, acuminate, quite entire or toothletted [6]. It has a very ſtrong ſmell of Camphor, whence both its names.

3. Stem thick, warted. Leaves ſcattered, naked, linear, ſerrate at the tip. Flowers terminating ſeſſile [7]. Calyx hemiſpherical, conſiſting of many leaves in a double row: leaflets herbaceous, acuminate, almoſt equal, pubeſcent on the outſide. Receptacle flattiſh, with the chaffs of the ſame length with the florets of the diſk. Florets of the ray neuter, with ovate-lanceolate, quite entire, yellow petals:—of the diſk androgynous, tubular; the corollets when mature arched at the baſe into a hemiſpherical ſpongy calyptra, or veil, covering the top of the ſeed. Theſe florets are ſucceeded by oblong ſeeds, ſomewhat convex, and grooved on one ſide, flat on the other, of a brown bay colour. They have no pappus; but in its ſtead a rim, that is ſomewhat waved, quite entire, covered by the veil of the corollet, ſurrounding a little ſhort white papilla, placed on the very ſummit of the ſeed. This ſpecies differs ſo much from the preceding, that it might conſtitute a ſeparate genus [8].

4. Stem erect, proliferous, not thickened: branches a little pubeſcent. Leaves ſcattered, erect, narrow-lanceolate, naked or very little pubeſcent, ſtriated, nerved underneath. Flowers terminating, ſolitary, ſeſſile. The inner row of the ſcales of the calyx lanceolate, the ſame length with the diſk of the corolla, and therefore the calyx is rayed. Corolla yellow [9].

Theſe are all ſhrubs, natives of the Cape of Good Hope.]

OSMUNDA.

[*Lin. gen. n.* 1172. *Reich. n.* 1289. *Schreb. n.* 1622. *Tournef. t.* 324. *Juſſ.* 15.

Frond bipinnate, pinnas cordate-lanceolate ſerrate.

25. Oſmunda lancea.
Lin. ſyſt. 928. *Thunb. jap.* 330.
Frond bipinnate, pinnas lanceolate ſerrate.

26. Oſmunda diſcolor.
Forſt. flor. auſtral. n. 413.
Fronds pinnate, pinnas oblong ſharpiſh entire ſeſſile alternate approximating.

27. Oſmunda procera.
Forſt. flor. auſtral. n. 414.
Fronds pinnate, pinnas remote ovate-oblong acuminate ſerrate ſeſſile.

DESCRIPTIONS, *&c.*

Some of the ſpecies (as Struthiopteris, Spicant and criſpa) do not belong to this genus, having the elaſtic ring common to the dorſiferous Ferns, or Ferns properly ſo called. *O. Spicant* is referred to *Blechnum* by ſome, to *Acroſtichum* by others, to *Struthiopteris* by Haller, Scopoli and Weis. *O. criſpa* is referred to *Pteris*; Villars make it an *Acroſtichum*; old authors in general name it an *Adiantum*. Till the genera of Ferns are better arranged, I have left the ſpecies as I find them in the 14th edition of *Syſtema Vegetabilium*; though there is no doubt of the ſpecies named above being eſſentially different from the genuine Oſmundas.

1. Plant a foot high, with a naked ſtem, terminated commonly by ſeven, petioled, undivided, lanceolate leaves, placed in a ring, and erect; among them riſes a cylindrical, peduncled ſpike[b]. Native of Ceylon and Amboina.

2. Root fibrous. Plant three, four, or five inches high, ſometimes a little higher. The ſtem divides in the middle into two branches, one of which immediately puts forth leaflets on each ſide; the other ſupports a naked flowering raceme[c]. Pinnas of the frond fleſhy, creſcent-ſhaped, ſemi-circular and halbert-ſhaped, irregularly ſcolloped, from three to eight pairs with an odd one. Spike or rather panicle from one to two inches long[d]. The branches lean one way; two rows of globular capſules are affixed to them, green at firſt, but yellow when ripe, and burſting vertically from the top to the baſe. Theſe capſules are divided by an annular zone, and contain numerous, oval, duſt-like ſeeds[e].

Weis thus deſcribes the fructification.—About the origin of the leaf, comes out a ſingle floral ſcape, which is a continuation of the ſtem; it is from an inch to two inches in length, branched, the branches commonly oppoſite, three, four, to ſix or ſeven and even more on each ſide, ſimple or ſomewhat branched, to which roundiſh capſules are fixed in a ſort of raceme, cloſely heaped in a double row, green at firſt, but turning yellow, and gaping widely from the top towards the baſe.

Linneus obſerves, that within the baſe of the ſtem, early in the ſpring, we may find a complete rudiment of the next year's plant.

Mr. Woodward remarks, that Moon-wort ſo exactly reſembles *Ophioglaſſum vulgatum* in habit and ſtructure, that they ought by no means to be ſeparated.

The difficulty, ſays Monſ. Villars, of meeting with this plant, which is not common, and lies concealed among graſs, the ſingularity of its leaves, the ſuperſtitious reveries of Matthiolus, who has attributed ſupernatural virtues to it, all conſpire to make it ſought after by philoſophers, herbariſts, and thoſe who hunt after wonderful ſecrets and the philoſopher's ſtone. After all, it is merely vulnerary, aſtringent, and a little mucilaginous.—Native of moſt parts of Europe in dry paſtures; flowering from may to july.—With us, near Linton and Chippenham in Cambridgeſhire; Colcheſter in Eſſex; Bury in Suffolk; Stratton-heath in Norfolk; Shotover-hill, and North-Leigh-heath in Oxfordſhire; Scadbury-park, Maidſtone, Blackheath and Cheſſelhurſt-common in Kent; north ſide of Bredon-hill and near Stourbridge in Worceſterſhire; near Bath in Somerſetſhire; Nottinghamſhire; Lancaſhire; near Settle and Ingleton in Yorkſhire; in mountainous paſtures of Weſtmoreland; in Scotland, on Ardgath-hill, to the north of Linlithgow; near Dundonald's, two miles from Little Loch Broom, on the weſtern coaſt of Roſs-ſhire, in the iſle of Skye, &c. In Ireland, on the riſing ground of a meadow two hundred yards north of the ſecond Lock of Lagan canal, found by Mr. John Templeton of Orangegrove near Belfaſt.

There are ſeveral varieties of this curious little plant, with ſeveral leaves and ſpikes, and with the leaves cloven.

3. Native of North America.

4. Root compoſed of numerous filiform fibres in bundles, with few fibrils. Stipe ſimple at bottom, an inch high, and then dividing into a frond and a floriferous ſcape. Frond ſolitary, petioled, ſuper-decompound-ternate, ſmooth: petiole compreſſed a little, a finger's length, triternate below, naked, leafy above, bipinnate. Pinnas and pinnules alternate, gaſhed, very finely ſerrate. Scape from the baſe of the petiole, roundiſh, ſtriated, erect, naked, ſmooth, twice as long as the frond, drooping and flowering at top. Spike branched: ſpikelets alternate, with globular capſules.

Native of Japan, about Nagaſaki, flowering in october and november[f].

5. Native of South America.

6. Root a bundle of ſmall fibres. Stems ſix or ſeven, a foot high, brittle, green with brown hairs. On the upper part of theſe are two oppoſite fronds, an inch and half long, and half an inch wide, mucronate, toothed on the edge, green and ſmooth on the upper ſurface, but loaded with white hairs on the under. From the baſe of the fronds ariſe two ſcapes, half a foot long, ſlender, covered with a ſilky lanugo, and terminated by erect, pyramidal racemes, two inches long[g].

Found by Plumier in the iſland of Martinico.

7. This riſes a foot or more, and is higher than the next ſpecies. In its higher ſpikes, which are double, it exactly agrees with it, only the pinnules are longer, narrower, not cut quite into the midrib, and of a paler green colour, ſomething in their diviſions, like the leaves of *Matricaria*.

8. This is ſometimes about a foot, but moſtly ſix or ſeven inches high, having a very ſlender green ſtalk, at firſt coming out of the earth of a dark colour. At about four inches from the ground, out of one ſide of the ſtalk ariſes one branch, on which twigs are ſet alternately, having ſeveral broad irregularly figured roundiſh pinnules, ſometimes deeply cut, at other times a little indented on the edges, of a pale green colour, like Adiantum album, and having many furrows ap-

[b] Linn. zeyl. [c] Scopoli. [d] Woodw. and Withering. [e] Lightfoot. [f] Thunberg. [g] Plumier. amer. 18. t. 26. and Moriſon.

pearing

pearing radiated. From the axil of this branch riſe two round, ſmall, green ſtalks, two inches long, towards the tops of which are ſeveral ſmall bunches of capſules, at firſt green, afterwards ferruginous. The root is covered with blackiſh hair, having ſeveral fibrils.

Both natives of Jamaica, by the banks of Rio Cobre [b].

9, 10, 11. Found in South America by Plumier.

12. This alſo is a native of Jamaica, where it was found by Swartz.—According to the Preſident of the Linnæan Society, it is a ſpecies of *Acroſtichum*.

13. Native of Jamaica, where it was found by Swartz.

14. Found in South America by Plumier.

15. Root thick, externally fibrous, and covered with thin brown ſcales. Plant from two to four feet high, of a pleaſant tranſparent green. Pinnules of the frond from ſix to ten pairs with an odd one at the end, each about two inches long, lanceolate or linear-lanceolate, blunt, finely but indiſtinctly ſerrated, divided by a midrib, from both ſides of which ariſe numerous fine biſid dichotomous nerves, their ramifications capillary and parallel; the lower and younger ones often lobed at the baſe. The central leaves are terminated by a bipinnate branch of fructifications; the pinnules awl-ſhaped, and crowded with ſeſſile cluſters of globular capſules, green when young, but reddiſh brown when ripe, and burſting vertically. The external leaves are barren [l].

Native of ſeveral parts of Europe, and alſo of Virginia, in watery places and bogs; it is the largeſt and handſomeſt of our Britiſh Ferns, and is found near Yarmouth and St. Faith's Newton bogs near Norwich; in the New Foreſt; in Cornwall; in the iſle of Angleſea; in ſeveral parts of Scotland; in Ireland, where it is called *Bog Onion*, in Kirkiſtown bog [m]. In Gerarde, the names are Water Fern, Oſmund the Waterman, St. Chriſtopher's herb.

This is the only ſpecies of Oſmunda which is noticed by Mr. Miller.

16. Linneus remarks, that O. regalis connects the preceding with this, and that this connects the following ſpecies with that.—Native of North America. Introduced in 1772, by Samuel Martin, M. D. It flowers in auguſt [n].

17. Frond leafy, more than a foot high, ſimply pinnate, with a chaffy ſtock. Pinnas ſeſſile, enſiform, tranſverſely ſtriated, ſerrulate, approximating, cordate at the baſe, embracing, even. Scape formed of the fructifying frond. Pinnas linear, diſtich, alternate, remote, a finger's length, the thickneſs of a gooſe-quill, rolled back at the edge, covering at firſt the fructification, and afterwards the diſk between the margins, as in *Acroſtichum*.—Native of the Cape of Good Hope [o].

18. Native of North America. Introduced in 1772, by Samuel Martin, M. D. It flowers in june [p].

19. The fronds grow in a ring, forming a hollow diſk, as in *Aſplenium Nidus* and *Scrophularia nodoſa*, and thus affording an aſylum to ſome of the Amphibia and the neſt of Birds [q].—Native of the north of Europe. Cultivated in 1760, by Peter Collinſon, Eſq.[r]

20, 21. Natives of Jamaica [s].

22. Several barren leaves proceed from one fibrous root, diſpoſed in a ring, half upright or reclining, from a ſpan to a foot in length, reſembling thoſe of Common Polypody, ſimple and pinnatifid; the pinnas cloſe, alternate, lanceolate, oblong, about two lines broad, quite entire, curved upwards; the middle ones largeſt, an inch or an inch and half in length; the upper and lower ones ſhorter, ribbed, the edge cartilaginous, very ſlightly notched, and bent backwards. Stipe or midrib beſet on the lower part with ſmall brown ſcales. From the centre of theſe leaves ariſe others bearing the fructifications; theſe are alſo pinnated, but twice as long, and more ſlender; the pinnas looſely ſet and alternate, a line in breadth; the middle ones longeſt, the upper and lower ones gradually decreaſing [t]. The narrow ſegments of theſe fertile leaves are remote from each other, the confluence however may almoſt always be traced, and towards the bottom of the leaf gives a waved appearance to the midrib [u]. Capſules cloſely crowded together, forming two diſtinct lines, parallel with the edges of the leaf, at firſt of a yelloviſh colour, becoming brown as they ripen [v]. Fructifications covered at firſt with a thin membrane. Capſule one-celled, two-valved, connected by an annular elaſtic cord, containing many minute ſeeds [w].

Dr. Withering, who in his ſecond edition had made this Fern an *Acroſtichum*, in his third introduces it as a *Blechnum*, in compliance with the opinion of Dr. Smith and Mr. Robſon, though from the narrowneſs of the leaflets it is not eaſy to determine whether the rows of capſules may more properly be conſidered as contiguous and parallel to the midrib, which is the character of that genus, or as diſpoſed along the edge of the leaf, which would refer it to the *Pteris*. It appears however from Hedwig's microſcopical diſſections, that the anthers are found upon the midrib; and that circumſtance ſeems ſufficient to determine that the rows of capſules more properly belong to that than to the edge of the leaf, notwithſtanding Hedwig himſelf has determined it to belong to the genus *Acroſtichum*.

Wherever botaniſts may at length agree to fix this Fern, it is clear that it cannot be an *Oſmunda*.

Rough Spleenwort is native of ſeveral parts of Europe, in woods and on moiſt heaths; producing its fructifications from july to ſeptember. It is not uncommon in Britain.

23. Leaf-ſtalks from two to ſeven inches long, waved, green. Leaf from an inch and half to three inches long. Leaflets of the barren leaves wedge-ſhaped and ſnipt at the edge; thoſe of the fertile leaves much narrower, linear or linear-lanceolate, and entire [x]. Fructifications in lines along the under margin of the leaflets, which is rolled back upon them, as in *Pteris aquilina*: after the diſcharge of the ſeeds increaſing in breadth ſo as to cover the whole diſk, except the midrib [y]. Capſules ſurrounded with an elaſtic ring: and therefore this Fern is not an Oſmunda [z].

Mr. Lightfoot remarks, that the outer barren leaves are ſmooth; the extreme pinnules of an obtuſe rhomboidal figure, plane, and toothed on the edges: the central fertile ones have the outer pinnules oval, convex, peduncled, their edges contracted, and the under ſides covered with yellow duſt-like fructifications.

Native of ſeveral parts of Europe, as Switzerland, Denmark, the South of France, Italy and Britain. With us in the county of Rutland; Cader Idris in Wales; Shap, near Kendall, &c. in the northern counties, on rocks, heaths and old walls, common. On rocks and ſtones upon the highland mountains of Scotland. The fructifications are ripe in ſeptember.

24. Stipe of the frond round, yellow, ſmooth. Frond bipinnate, with an odd leaflet. Pinnas oppoſite and alternate, oblique at the baſe, cordate, oblong, blunt, ſerrulate with a reflex margin, marked with lines, ſmooth, green above, pale beneath, an inch and half long. Fertile fronds diſtinct, bipinnate: pinnas oppoſite and alternate, linear-lanceolate. It differs from *O. regalis*, which it reſembles very much, in having the fertile fronds diſtinct.—Native of Japan, flowering in april and may.

25. This alſo has the fertile fronds diſtinct, with the flowering ſpikes ſuperdecompound ternate. Pinnas generally oppoſite, the upper ones quite ſo: pinnules alternate, ſeldom nearly oppoſite, lanceolate, very finely ſerrate, attenuated both ways, ſmooth, an inch or an inch and half long.—Native of Japan, flowering in april and may [a].

26, 27. Natives of New Zealand [b].

PROPAGATION AND CULTURE.

Oſmund Royal and the other European ſorts, except Moonwort, will grow in a moiſt ſhady ſituation in gardens: but will not thrive very well without bog earth. Moonwort muſt have a dry ſituation.

OSMUNDA. See *Blechnum, Onoclea, Pteris.*]

OSSIFRAGA. See *Euphorbia.*

OSTEOSPERMUM. (Οστεον σπερμα, *bony seed.*)

Lin. gen. n. 992. *Reich. n.* 1075. *Schreb. n.* 1341. *Gærtn. t.* 168. *Juss.* 183. Monilifera. *Vaill. mem. par.* 1720. *f.* 28. Chrysanthemoides. *Tournef. mem. par.* 1705. *f.* 4. *Dill. gen. 9. elth.* 68.

Class. 19. 4. Syngenesia Polygamia Necessaria.

Nat. order of *Compositæ Discoideæ. Corymbiferæ*, Juss.

GENERIC CHARACTER.

CAL. *Common* simple, hemispherical, many-leaved: *leaflets* awl-shaped, small.

COR. *Compound* rayed. *Corollets* hermaphrodite very many, in the disk. Females about ten in the ray.

Proper, of the hermaphrodite tubular, five-toothed, the length of the calyx:—of the female ligulate, linear, three-toothed, very long.

STAM. in the hermaphrodites, *Filaments* five, capillary, very short. *Anther* cylindrical, tubulous.

PIST. in the hermaphrodites, *Germ* very small. *Style* filiform, scarcely the length of the stamens. *Stigma* obsolete.—In the females, *Germ* globular. *Style* filiform, the length of the stamens. *Stigma* emarginate.

PER. none. *Calyx* unchanged.

SEEDS in the hermaphrodites none:—in the females solitary, subglobular, coloured, at length hardened, inclosing a kernel of the same shape. *Pappus* none.

REC. naked, flat.

ESSENTIAL CHARACTER.

Cal. simple or in two rows many-leaved, almost equal. *Seeds* globular, coloured, bony, (berried or nucamentaceous, *G.*) *Down* none. *Recept.* naked.

SPECIES.

1. Osteospermum spinosum. *Prickly Osteospermum.*
Lin. spec. 1308. *Syst.* 792. *Reich.* 3. 930. *hort. cliff.* 404. *mant.* 480. *Berg. cap.* 331.

Leaves lanceolate mucronate subpetioled smooth serrate, branchlets angular-toothletted.

3. Osteospermum moniliferum. *Poplar-leaved Osteospermum.*
Lin. spec. 1308. *Reich.* 3. 931. *hort. cliff.* 423. *Berg. cap.* 331. *Gærtn. fruct.* 2. 424. *Dill. elth.* 80. *t.* 68. *f.* 79. (Chrysanthemoides). *Pluk. amalth. t.* 382. *f.* 4. *Breyn. cent.* 155. *t.* 76. (Chrysanthemum). *Vaill. act.* 1720. *p.* 573. (Monilifera).
Leaves obovate serrate petioled subdecurrent.

[4. Osteospermum ilicifolium. *Holm-leaved Osteospermum.*
Lin. spec. 1308. *Reich.* 3. 931. *Burm. zeyl.* 172. *t.* 62.
Leaves oblong tooth-angulate rugged half-embracing, branches grooved.

5. Osteospermum ciliatum. *Fringe-leaved Osteospermum.*
Lin. syst. 793. *Reich.* 3. 932. *Berg. cap.* 332. *Burm. afr.* 171. *t.* 61. *f.* 2.
Leaves elliptic-lanceolate crenate ciliate.

6. Osteospermum junceum. *Reedy Osteospermum.*
Lin. syst. 793. *Reich.* 3. 932. *mant.* 291. *Berg. cap.* 334.
Leaves linear acute keeled distant, panicle terminating.

7. Osteospermum triquetrum.
Lin. syst. 793. *Suppl.* 385.
Leaves linear three-sided.

8. Osteospermum corymbosum.
Lin. syst. 793. *Reich.* 3. 932. *mant.* 290.
Leaves lanceolate smooth, flowers panicled.

9. Osteospermum imbricatum.
Lin. syst. 793. *Reich.* 3. 932. *mant.* 290.
Leaves ovate blunt imbricate.

10. Osteospermum herbaceum.
Lin. syst. 793. *Suppl.* 385.
Leaves ovate subsessile spatulate serrate, stem herbaceous.

11. Osteospermum niveum.
Lin. syst. 793. *Suppl.* 386.
Leaves ovate petioled toothed woolly.

12. Osteospermum perfoliatum.
Lin. syst. 793. *Suppl.* 386.
Leaves ovate petioled angular-toothed tomentose underneath, petioles perfoliate-embracing.]

13. Osteospermum polygaloides.
Lin. spec. 1308. *Syst.* 793. *Reich.* 3. 933. *mant.* 480. *Berg. cap.* 333. *Pluk. mant.* 47. *t.* 382. (Chrysanthemum).
Monilifera polygalæ foliis. *Vaill. act.* 1720. *p.* 374.
Leaves lanceolate scattered decurrent smooth quite entire, axils woolly.

[14. Osteospermum calendulaceum.
Lin. syst. 793. *Suppl.* 386.
Leaves lanceolate setose toothed rugged, stem fleshy lax.

15. Osteospermum Arctotoides.
Lin. syst. 793. *Suppl.* 385.
Leaves lyrate petioled, petioles eared at the base half-embracing tomentose.

16. Osteospermum rigidum. *Rigid Osteospermum.*
Ait. hort. kew. 3. 275.
Leaves tooth-pinnatifid hairy, branches unarmed.

17. Osteospermum cæruleum. *Blue-flowered Osteosperm.*
Jacqu. collect. 1. 78. *Ait. hort. kew.* 3. 275.
O. pinnatifidum. *L'Herit. stirp. nov. p.* 11. *t.* 6.
Leaves pinnate, pinnas toothed.]

DESCRIPTIONS, &c.

1. This is a low shrubby plant, which seldom rises above three feet high, and divides into many branches; the ends of the shoots are beset with green branching spines; the leaves are very clammy, especially in warm weather; they are long and narrow, and set on without any order. The flowers are produced singly at the ends of the shoots; they are yellow, and appear in july and august.

[It is very nearly allied to the next species. The fruit hangs down on an oblong peduncle, and consists of dusky-purple, bony, globular berries disposed in a ring[a].

Native of the Cape of Good Hope. Cultivated in 1700 by Dr. Uvedale. It flowers from february to october[b].

2. The angles of the branches are toothletted by the back of the petioles running down, and are frequently wholly involved in wool, which disappears with age. Leaves wedge-form, crose. Peduncles scaly. Flowers small. Seeds obovate[c].]

Stem four or five feet high, dividing into many branches towards the top, which spread out flat on every side; they have a purplish bark. Leaves of a thick consistence and succulent, alternate, of a light green colour, from two to three inches long, and one inch broad in the middle. The flowers stand single upon long axillary peduncles, which have a few very small leaves growing alternately their whole length. Berry oval, at first green, then red, but when fully ripe of a dark-purple colour, having a thin pulp, which covers one hard seed[d]. The leaves are more pointed than in *O. moniliferum*, of a green colour, and acutely serrate; the petioles are bordered, and the leaves are deeply veined. It produces tufts of yellow flowers at the extremity of the shoots, from spring to autumn, and frequently ripens seeds. [It was cultivated in 1757, by Mr. Miller[e].

3. This rises with a shrubby stalk seven or eight feet high, covered with a smooth gray bark, and dividing into several branches. Leaves alternate, of a thick consistence, covered with a hoary down, which goes off from the older leaves, unequally indented on their edges. Flowers in clusters at the ends of the branches, six or eight coming out together on petioles an inch and half long; they are yellow, and shaped like those of Ragwort (Senecio Jacobæa) having about ten ligulate florets in the ray.

[Receptacle flat, in the elevated middle dotted, towards the circumference hollowed out in small pits for the reception of the fertile seeds, naked, smooth.

[a] Linn. mant. [b] Hort. kew. [c] Linn. spec. [d] Mill. fig. [e] Hort. kew.

Seeds ovate-globular, berried, dark-purple, ſmooth, bald; covered with three integuments, the outer fleſhy, thin, the middle cruſtaceous, thick, hard, the inner membranaceous, pale ruſſet: the fleſhy integument is wanting in moſt of the ſpecies, and thus the ſeed from being berried becomes nucamentaceous [s]. Linneus remarks, that the petioles have a knob under their baſe.]

This plant flowers but ſeldom in England. The time of its flowering is july or auguſt. [It was cultivated here in 1714 [t].

4. Leaves ſeſſile, almoſt embracing, angular with three teeth on each ſide, rolled in at the edge, mucronate at the angles, above rugged, beneath villoſe and almoſt woolly [l].

5. This is a woolly ſhrub, with oblong toothed or notched and ciliate leaves [k].

6. Stem five feet high, upright, ſtiff and ſtraight, even. Leaves awl-ſhaped or linear, ſtiff, even, ſeſſile, very remote. Peduncles one-flowered, thin, ſtiff, with awl-ſhaped remote leaflets ſcattered over them [l].

7. Stem ſuffruticoſe. Leaves even, a finger's length, abundant. Flowers from the uppermoſt axils, ſolitary, peduncled, yellow. Calyx like that of Geropogon, imbricated, with few, ſharp ſcaleets [m].

8. Stem upright, determinately branched, even, the thickneſs of a finger. Leaves alternate, ſeſſile, veinleſs, ſtiff, a finger's length, on the flowering branches ſmaller, rugged at the edge. Panicle terminating, corymboſe, with clammy-villoſe peduncles. Flowers yellow. Seeds berried, oblong, larger than grains of wheat [n].

9. Stem determinately branched, two feet high, ſcarred. Leaves cluſtered, ſeſſile, ovate or obovate, ſubimbricate, quite entire, even, embracing, clammy about the edge with very ſhort hairs, and the axils villoſe. Peduncle terminating, filiform, the length of the flower, one-flowered, pubeſcent, leafleſs. Calyx ſimple. Corolla yellow.

It differs from O. polygaloides, in not having the leaves lanceolate, or acute, or keeled; and the peduncles without a linear leaflet [o].

10. This reſembles a *Verbeſina*. Leaves exactly ſpatulate; the ſpatule ovate, acutely ſerrate.

11. The whole herb is covered with a thick and very white lanugo.

12. This is ſingular in having the petiole dilated at the inſertion, like a little wheel round the ſtem [p].]

13. Stalk about four feet high, dividing into many ſmall branches. Leaves ſmall, oblong, ſeſſile, on ſome of the upper branches imbricate. The flowers come out at the end of the branches, ſtanding ſingly on peduncles about an inch long.

[The ſtem between the leaves has frequently villoſe hairs on it like thoſe on the bag of the ſilk-worm. Leaves ſeſſile, erect, mucronate, keeled. Peduncles and calyxes muricated with very ſoft ſpines [q]. Cultivated by Mr. Miller, in 1759.

14. This reſembles *Calendula arvenſis* very much, and thence has its name; but it differs in the ſeeds not being winged, but cylindrical, bony and ſmooth.

15. In the ſurface, the figure of the herb, and leaves, and almoſt in the flower, this ſpecies reſembles an Arctotis, but in the ſmoothneſs of its ſeeds an Oſteoſpermum [r].

16. Introduced by Mr. Francis Maſſon in 1744. It flowers from april to july [t].

17. This is an underſhrub, three feet high, with a ſtrong ſmell. Root woody, branching, fibrous. Stem ſomewhat woody, erect, round, regularly branched, gray. Leaves alternate, ſpreading: ſegments alternate, (ſome almoſt oppoſite,) oblong, acute, ſerrate; the lower ſinuſes wider, deeper, parallel to the midrib; the upper ones rounded; they are without veins, and have only one nerve prominent beneath; they are of the ſame colour on both ſides, and fragrant, from an inch and half to two inches in length, and fifteen lines in breadth. Petioles half the length of the leaves, broadiſh, gibbous on one ſide, channelled on the other, widened at the baſe, with two teeth on each ſide, almoſt half embracing, ſcarcely pubeſcent. Flowers terminating, very looſely corymbed, peduncled, erect, blue, an inch wide. Peduncles from the upper leaflets, alternate, very long, from upright divaricated, one-flowered, ſomewhat rugged and viſcid; having one or two linear bractes on them. Calycine leaflets linear, acute, erect, almoſt equal. Female florets above twenty in the ray, ſcarce viſibly three-toothed, ſlightly two-grooved, ending in a filiform villoſe-glandular tube, twice as long as the hermaphrodites, which are longer than the calyx, with the tube narrowing at bottom like a pedicel and villoſe, the border ſharp, erect. Seeds obovate, ſomewhat angular and rugged, not at all bony [l].

Introduced by Mr. Francis Maſſon in 1774 [s].

All theſe ſhrubs are natives of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

Theſe plants being too tender to live in the open air in England, are placed in the green-houſe in october, and may be treated in the ſame manner as Myrtles, and other hardy green-houſe plants, which require a large ſhare of air in mild weather; and in the beginning of may the plants may be removed into the open air, and placed in a ſheltered ſituation during the ſummer ſeaſon. The firſt and ſecond ſorts muſt have plenty of water, being very thirſty plants.

They are propagated by cuttings, which may be planted in any of the ſummer months, upon a bed of light earth, and ſhould be watered and ſhaded until they have taken root, which they will in five or ſix weeks, when they muſt be taken up and planted in pots; for if they are ſuffered to ſtand long, they will make ſtrong vigorous ſhoots, and will be difficult to tranſplant afterward, eſpecially the ſecond and third ſorts; but there is not ſo much danger of the firſt, which is not ſo vigorous, nor ſo eaſy in taking root as the other. During the ſummer ſeaſon the pots ſhould be frequently removed, to prevent the plants from rooting through the holes in the bottom of the pots into the ground, which they are very apt to do when they continue long undiſturbed, and then they ſhoot very luxuriantly; and, on their being removed, theſe ſhoots, and ſometimes the whole plants, will decay.

Leaves ovate floriferous.]

DESCRIPTIONS, *&c.*

1. This is a very low ſhrub, ſeldom riſing above two feet high, having woody branches. Leaves long, narrow, of a bright colour. Flowers of a yellowiſh colour; ſucceeded by berries, which at firſt are green, and afterwards turn to a bright red colour, like thoſe of Aſparagus.

[According to Scopoli, it is from a foot to two feet in height. He obſerved rudiments of ſtyles and a germ in the male plant: and aſks why it has the epithet of *alba* or white, when the calyxes and almoſt the whole plant are yellow. He calls the fruit a dry umbilicated berry; and joins the *Hippophae* with it.

Linneus remarks, that the female ſhould rather be called an hermaphrodite, ſince it has ſtamens, although it is barren without the male.

Native of France, Spain, Italy, Carniola and mount Libanus. Cultivated in 1739, by Mr. Miller*.

2. Stem ſhrubby, tubercled, a fathom high. Branches alternate, bending, round, upright, ſmooth. Leaves alternate, frequent at the ends of the branches, acuminate, ſerrate with ſetaceous notches, nerved, paler underneath, ſmooth on both ſides, unequal, an inch long and more. Petioles one-third of the length of the leaves. Flowers from the midrib of the upper ſurface of the leaves in umbels, male and female on diſtinct ſhrubs. Umbels ſimple, with about eight flowers without an involucre. Peduncles capillary, unequal, ſmooth, a line in length. Perhaps it may form a new genus, but the female flowers being yet unknown, it cannot be ſettled ſatisfactorily. The leaves are ſaid to be eaten in Japan, where it is a native†.]

PROPAGATION AND CULTURE.

This plant grows by the ſide of roads, as alſo between rocks, is with great difficulty tranſplanted into gardens; nor does it thrive after being removed, ſo that the only method to obtain this plant is, to ſow the berries where they are to remain. Theſe berries commonly remain a year in the ground before the plants appear, and ſometimes they will lie two or three years, ſo that the ground ſhould not be diſturbed under three years, if the plants do not come up ſooner. Theſe ſeeds muſt be procured from the places where the plants naturally grow, for thoſe which have been brought into gardens never produce any, and it is with great difficulty they are preſerved alive.

Doria africana arboreſcens, floribus ſingularibus. *Dill. elth.* 123. *t.* 103. *f.* 123.
Leaves oblong quite entire, ſtem arboreſcent fleſhy, with woolly ſcars.

DESCRIPTIONS, &c.

1. This is very diſtinct by its ſmooth fleſhy ſtalk like the Cacalias, and the flower of Othonna. The ſcars of the leaves are round and tomentoſe [a]. Introduced in 1774, by Mr. Francis Maſſon. It flowers from may to november [b].]

2. This has a thick ſhrubby ſtalk, dividing into ſeveral branches which riſe five or ſix feet high; the leaves come out in cluſters from one point, ſpread on every ſide; they are ſmooth, narrow at their baſe, enlarging gradually to their points, which are rounded their edges are acutely indented like thoſe of the Holly. From the center of the leaves ariſe the foot-ſtalks of the flowers, which are five or ſix inches long, branching out into ſeveral ſmaller, each ſuſtaining one yellow radiated flower, ſhaped like the former; theſe are ſucceeded by ſlender ſeeds crowned with down.

[The floral leaves at the peduncles are often oppoſite. Peduncles frequently in pairs. Calyxes five-parted. It is one of the moſt variable plants we have:—being herbaceous, 1. with ovate, quite entire leaves. 2. With the root-leaves pinnate, quite entire. 3. With the leaves linear, very narrow. 4. With the leaves lanceolate, quite entire. 5. With the leaves lanceolate, toothed. 6. With the leaves lanceolate-ſubelliptic. 7. With the leaves ſublanceolate, three-toothed.—Or ſhrubby: 8. With the leaves of the top lanceolate, ſubſeſſile. 9. With the leaves alternate, lanceolate, toothed [c].

Introduced in 1774, by Maſſon. It flowers in may and june [d].

[a] Linn. mant. [b] Hort. kew. [c] Linn. ſpec. [d] Hort. kew.

3. Intro-

3. Introduced in 1774, by Maſſon. It flowers from april to july [a].

4. Root annual. Stem filiform, flexuoſe. Calyx pitcher-ſhaped, with about fourteen teeth at the edge. Ray many-flowered [b].

5. Stem ſhrubby, proliferous, ſpreading, duſky. Leaves ſcattered, ſemitrifid, ſomewhat fleſhy, with a white wool in the axils of the leaves. Peduncles axillary, ſolitary, one-flowered, much longer than the leaves. Calyxes deeply divided. Seeds white with wool [c].]

6. This riſes with a ſhrubby ſtalk about the thickneſs of a man's thumb, two or three feet high, dividing into many branches, covered with a hoary down. Leaves hoary, about three inches long and one broad, cut into many narrow ſegments almoſt to the midrib; theſe ſegments are equal and parallel, and have two or three teeth at the end. The flowers are produced on long axillary peduncles towards the ends of the branches; they have large yellow rays; and are ſucceeded by oblong purple ſeeds crowned with down.

[Linneus remarks that the whole plant is often tomentoſe. Stem ſcarred.

It flowers in may and june, and was cultivated in 1731, by Mr. Miller [d]: who ſays that] the ſeeds were ſent to Holland from the Cape, and plants raiſed from them, in the Amſterdam garden, in 1699.

7. This has a low, ſhrubby, branching ſtalk. The leaves are thick, like thoſe of Sampire, and are cut into many narrow ſegments. The flowers are produced on ſhort peduncles at the ends of the branches; they are yellow, and the ſeeds are brown.

[Cultivated in 1759, by Mr. Miller. It flowers from january to march [e].

8. Stem ſhrubby, like that of Athanaſia, proliferous, even. Leaves alternate, remote, three-paired with an odd leaflet, naked. Flower rather large, terminating, from the dichotomy; on a one-flowered peduncle, twice as long as the leaves and round. Calyx even. Corolla yellow, both in the ray and diſk; the former twice as long as the calyx. Seeds downy.

9, 10, 11. Found at the Cape by Thunberg.

12. This reſembles O. Ericoides very much, and differs only in having pinnatifid leaves [f].]

13. This riſes with a ſhrubby ſtalk four or five feet high, dividing into ſeveral branches. Leaves grayiſh, placed without order; thoſe on the lower part narrow and entire, but the others indented on the edges after the manner of Hart's-horn. The flowers are produced in looſe umbels at the ends of the branches, and are yellow.

[Receptacle narrow, ſomewhat convex, with hollows or cells in the middle; the edges of the cells are ſet with very ſhort, briſtly-ciliate hairs, giving the receptacle the appearance of being villoſe; next the edge are ſix or eight wider cells, receiving the germs of the female flowers. The ſeeds, which are the produce of theſe germs are largiſh, obovate, ſomewhat beaked at the baſe, ſtriated, with a ſilky hoarineſs. Down very abundant, capillary, white-ſilky, three times as long as the ſeed [g].

Cultivated in 1731 by Mr. Miller. It flowers from july to ſeptember [h].]

14. This has a ſtrong fibrous root, which ſhoots deep in the ground, and ſends out many woody ſtems, which ſpread on every ſide, and trail upon the ground. Leaves grayiſh, ſeſſile, and of a thick conſiſtence, narrow at the baſe, enlarging upwards, and broad at their points, where they are rounded. The flowers are produced upon long thick ſucculent peduncles at the ends of the branches, and from the axils; they are yellow, the rays ſharp pointed, and not much longer than the calyx, which is cut into eight equal ſegments at top; the diſk is large, and the florets as long as the calyx. The ſeeds are crowned with long down.

It was diſcovered by Dr. Shaw growing naturally near Tunis in Africa. [Mr. Miller cultivated it in 1758; and it flowers from april to june [i].

15. This has round ſtalks, which at firſt are herbaceous and ſucculent, but by age become woody: they riſe three or four feet high, and divide into many branches from the bottom. Leaves thick and ſucculent, about two inches long, and one broad in the middle, of a gray colour, placed without order, and ſeſſile. The flowers are produced towards the end of the branches upon ſucculent peduncles about four inches long, each ſuſtaining one yellow flower, ſmaller than the preceding. It begins to flower in auguſt, and there is a ſucceſſion of flowers till the middle of winter [k].—Cultivated by Mr. Miller in 1758.

Linneus remarks that this ſpecies reſembles *O. cheirifolia*, but is upright and four feet high.

16. Stem ſhrubby, two feet high, even. Leaves alternate, petioled, broad-lanceolate; the upper ones deltoid, with one tooth on each ſide, ſmooth. Peduncles very long, even, ſtiff and ſtraight; with a few, very ſmall, very remote, lanceolate leaves, having one tooth on each ſide. Panicle ſmall, with little, yellow flowers, and a ſimple, even, eight-cleft calyx [l].

17. Stem from a foot to two feet high and more, even. Leaves alternate, even, ſpreading, declining a little, narrower at the baſe [m]. It did not flower with Linneus, though he cultivated it for a long time, but from the villoſe hairs at the baſe of the leaves, as in *O. fruticoſa*, he placed it in this genus, till greater certainty could be obtained.

Mr. Miller had made it a *Craſſula*, and ſays that it] riſes with a ſhrubby ſtalk, four or five feet high, dividing into many branches, which at firſt are taper and ſucculent, but by age become woody. The leaves are very ſlender, taper, ſucculent, flaccid, generally turning downward, eſpecially in winter, near three inches in length. It did not flower with him. It was ſent him from Leyden by Adrian van Royen. [According to the Kew catalogue it flowers in july; and was introduced in 1774, by Mr. Francis Maſſon.

18. Stem a ſpan high, filiform, even, with one or two one-flowered branches. Root-leaves linear, filiform, almoſt the length of the ſtem, woolly at the baſe: ſtem-leaves only three or four, ſimilar. Flowers terminating, ſolitary, the ſize of peas, yellow. Calyx commonly eight-leaved.

19. Root bulbous. It greatly reſembles *O. ciliata*, n. 9.

20. Root bulbous.

21. This is an upright ſhrub, with the ſtem the ſize of a ſwan's quill. Leaves ſcattered, ſeſſile, quite entire, ſmooth. Peduncles lateral, ſolitary, one-flowered. Flower roundiſh. Calyx commonly eight-cleft. Corolla yellow. The peduncles and receptacles of the preceding year remain dried up on the ſtem.

22. Root bulbous.

23. This is an upright ſhrub, reſembling Heath, commonly dichotomous. Leaves like thoſe of Heath, ſcattered, ſomewhat cluſtered, awl-ſhaped, ſhort, diſtant at the ſide, curved inwards, even. Peduncles axillary, ſtraight, even, one-flowered. Flower roundiſh, not large.

24. Root fibrous, very ſlender. Root-leaves, and one or two ſtem-leaves lyrate, an inch long, even. Stems upright, a palm high, filiform, with the branches finally ſetaceous and capillaceous, even. Flowers terminating, the ſize of Hemp ſeed, yellow. Calyx five-leaved, ovate, acute.

25. Stem ſhrubby, compound, erect, round. The young ſhoots quite ſimple; thoſe of the preſent and former year leafy. Leaves ſcattered in cluſters, ſmall in proportion to the plant, ſeſſile, almoſt erect, flat, even, with five or ſeven erect teeth; the lower ones ſhorter. Flowers from the upper part of the internodes, lateral, ſcattered, ſolitary, ſmall, like thoſe of Cotula. Peduncles one-flowered, longer than the leaf. Calyx ſeven-leaved, ſimple, acute, permanent. Ray ſmall, yellow, ſertile, with a bifid ſtyle. Diſk yellow, convex. Down ſimple, ſeſſile [n].

26. This is allied to the next ſpecies. Stem of the firſt year a foot high, upright, ſimple, round, even,

[a] Hort. kew. [b] Linn. ſpec. [c] Linn. ſuppl. [d] Hort. kew. [e] Idem. [f] Linn. ſuppl. [g] Gærtner. [h] Hort. kew. [i] Idem. [k] Miller's figures. [l] Linn. mant. [m] Idem. [n] Linn. ſuppl.

ſmooth. Leaves alternate, ſubpetioled, obovate, (the upper ones lanceolate, veinleſs, oleraceous, glaucous-green, like thoſe of Cabbage, with a minute point; the lower ones quite entire; the middle ones with two teeth at the baſe; the upper ones toothed at the ſides; all ſomewhat decurrent at the back. From each axil leaflets rudiments of branches. Peduncles from the top of the ſtem, a palm in length, one-flowered, alternate, few, filiform, erect, with a few minute leaflets. Calyx cylindric, blunt, equal, eight-cleft. Ray eight-petalled, yellow, lanceolate, three-toothed or thereabouts, twice as long as the calyx. Stigmas two, lanceolate, ſhort. Diſk yellow. Seeds of the ray very ſhort; with an abundant capillary down, the length of the calyx.

It differs from *O. arboreſcens* in having remote, toothed leaves, not cluſtered and quite entire, as in that; the ſtem without any hairy ſcars of the leaves; the ray eight-petalled not five-petalled; the ſtem round with ſmooth branches; the peduncles ſomewhat branched [a].

27. Height (at five years of age) one foot, with a ſtem the thickneſs of a human finger, reſembling *Sedum arboreſcens*, and like that fleſhy and woody, though never ſo tall or thick, pliant, covered with a browniſh aſh-coloured bark, not rough but rather ſmooth, and having white woolly tubercles ſcattered over it, which is peculiar to this ſpecies: the branches alſo have them, and are obliquely curved inwards: the ends of the branches and baſes of the leaves have a fine wool on them, not conglobated but ſcattered. The branches are otherwiſe naked, ſomewhat woody, covered with a bark like that of the ſtem, browniſh green towards the end, more tender and herbaceous; theſe leaves come out alternately at ſhort diſtances; they are oblong, wider towards the top and blunt, contracted towards the baſe, green on both ſides, ſomewhat glittering and as it were mealy, like thoſe of Auricula, flat, thickiſh, ſucculent and ſmooth, veinleſs, with only a white nerve protuberant underneath, and on the upper part a little hollowed next the baſe.

Among theſe leaves ſpring the peduncles, ſolitary or in pairs, round, tender, of a pale glaucous colour, having a woolly ſcale or jag near the middle, terminated each by a ſingle flower. Calyx oblong, with five roundiſh angles, five-cleft to the middle, glaucous-green, thick and ſucculent. Corolla yellow; with five florets in the ray, oblong and rather wide, ſituated at the end, ſlightly crenate in the middle, rolled back ſoon after they open: theſe are ſucceeded by thickiſh, ſhort, oblong-round ſeeds, at firſt whitiſh, but when ripe browniſh, crowned by a copious ſhort browniſh down: the ſeeds in the diſk are longer, ſlender, round and barren with a more ſlender whitiſh down.

This plant makes very ſlow progreſs here. In auguſt it puts out young leaves, which it keeps all the winter; the heads of flowers appear about the end of november, and do not open till the middle or end of january: in ſpring the leaves gradually drop off, and the plant appears as if dead till the ſucceeding autumn. Cultivated in Sherard's garden at Eltham in 1723 [a].

All the ſpecies, except the fourteenth, are natives of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

Theſe plants are preſerved in the dry ſtove, or even in the green-houſe, without any artificial warmth: it is ſufficient to protect them well from froſt; and in mild weather they muſt have a large portion of air. In ſummer place them in a ſheltered ſituation.

They may be increaſed during the ſummer months by cuttings, planted upon an old hot-bed, and covered with glaſſes, ſhading them from the ſun in the heat of the day. When they have taken root, plant each into a ſeparate pot filled with ſoft loamy earth, and place them in the ſhade till they have taken new root; then remove them to a ſheltered ſituation, where they may remain till autumn; treating them in the ſame way as the old plants.

14. The fourteenth will live in the open air, in a warm ſituation and a dry ſoil.

DESCRIPTIONS, *&c.*

1. A ſhrub. Leaves oppoſite, petioled, oblong, toothed [a]; the teeth terminated by ſpines, rigid. Flowers terminating, corymbed, ſubſeſſile among the terminating leaves. Berries black.

Native of South America; in the mountains of Hiſpaniola. The fruit is ripe in may [a].

2. This alſo is a ſhrub. Leaves oppoſite, petioled, ſmooth, very long. Corymbs dichotomous. Tube of the corolla very long [a]. Berry ſucculent, covered by the acutely triangular ſegments of the calyx, ſubglobular, one-celled, having four ſtones, when ripe drying up and diviſible into four parts. Cuticle when ripe ſomewhat ſpongy, wrinkled, faſtened to the back of the ſtones; which are regularly four, but two only commonly ripen, coriaceous-cruſtaceous, gibbous on one ſide, wrinkled, concave or angular on the other, one-celled. There is one ſeed in each ſtone, of the ſame ſhape with it, faſtened to its baſe, ruſeſcent [a].

Gærtner remarks, that the *Valdia* of Plumier is of a quite different genus, if the generic character be right which Adanſon attributes to it, in *Familles des plantes*, 2. 157.

28. Oxalis multiflora. *Many-flowered Wood Sorrel.*
Jacqu. monogr. 49. t. 15.
O. hirtæ varietas. *Jacqu. collect. 3. 223. ic. rar. vol. 3.*
Corollas bell-ſhaped, ſtyles very ſhort, leaflets wedge-ſhaped.

29. Oxalis rubella.
Jacqu. monogr. 50. t. 16.
O. hirta. *Jacqu. collect. 3. 232. ic. rar. vol. 3. Burm. afr. 71. t. 28. f. 2.*
Corollas bell-ſhaped, ſtyles middling, filaments toothleſs.

30. Oxalis roſacea.
Jacqu. monogr. 51. t. 17.
Corollas bell-ſhaped, ſtyles middling, filaments gibboſely toothletted.

31. Oxalis diſticha.
Jacqu. monogr. 52. t. 18.
Corollas bell-ſhaped, ſtyles middling, petioles wingedly ſtipuled.

32. Oxalis tenella.
Jacqu. monogr. 53. t. 19.
Subcauleſcent, corollas bell-ſhaped, filaments toothleſs, leaflets obcordate.

33. Oxalis reptatrix.
Jacqu. monogr. 54. t. 20.
Subcauleſcent, corollas bell-ſhaped, filaments toothletted, leaflets roundiſh.

B. *Stipitated.*

* *With ſimple leaves.*

34. Oxalis lepida.
Jacqu. monogr. 55. t. 21.
Styles very long.

35. Oxalis monophylla. *Simple-leaved Wood Sorrel.*
Lin. ſyſt. 432. Reich. 2. 388. mant. 241. Jacqu. monogr. 56. t. 79. f. 3. Thunb. diſſ. n. 1. t. 1. prodr. cap. 82.
Styles of middling length.

36. Oxalis roſtrata. *Beaked Wood Sorrel.*
Jacqu. monogr. 57. t. 22.
Styles very ſhort.

** *With binate leaves.*

37. Oxalis criſpa. *Curled Wood Sorrel.*
Jacqu. monogr. 58. t. 23.
Leaflets obovate curled.

38. Oxalis aſinina.
Jacqu. monogr. 59. t. 24.
Leaflets lanceolate, ſtyles middling.

39. Oxalis leporina.
Jacqu. monogr. 60. t. 25.
Leaflets lanceolate, ſtyles very long, filaments toothletted.

40. Oxalis lanceæfolia.
Jacqu. monogr. 61. t. 26.
Leaves binate and ternate, ſtyles very long, filaments toothleſs.

*** *With ternate leaves.*

41. Oxalis fabæfolia. *Bean-leaved Wood Sorrel.*
Jacqu. monogr. 62. t. 27.
Leaves obovate flat, petioles winged.

42. Oxalis laburnifolia. *Laburnum-leaved Wood Sorrel.*
Jacqu. monogr. 63. t. 28.
The middle leaflet ſublanceolate, the ſide ones obliquely oblong, ſtyles very long, filaments toothletted.

43. Oxalis ſanguinea. *Bloody-leaved Wood Sorrel.*
Jacqu. monogr. 64. t. 29.
The middle leaflet ſublanceolate, the ſide ones obliquely oblong, ſtyles middling.

44. Oxalis minuta. *Small Wood Sorrel.*
Lin. ſyſt. 432. Jacqu. monogr. 65. t. 79. f. 2. Thunb. diſſ. n. 2. t. 2.
Leaflets lanceolate acute, ſtyles very long, filaments toothleſs.

45. Oxalis ciliaris. *Ciliate-leaved Wood Sorrel.*
Jacqu. monogr. 66. t. 30.
Leaflets oblong blunt, ſtyles very long, filaments toothleſs.

46. Oxalis arcuata. *Bending Wood Sorrel.*
Jacqu. monogr. 67. t. 31.
Leaflets linear-oblong emarginate, ſtyles very ſhort.

47. Oxalis linearis. *Linear-leaved Wood Sorrel.*
Jacqu. monogr. 68. t. 32.
Filaments toothleſs, ſtyles very long, corollas caryophylleous, leaflets linear.

48. Oxalis gracilis. *Slender Wood Sorrel.*
Jacqu. monogr. 69. t. 33.
Filaments toothleſs, ſtyles very long, corollas bell-ſhaped, leaflets linear.

49. Oxalis reclinata. *Reclining Wood Sorrel.*
Jacqu. monogr. 70. t. 34.
Filaments toothleſs, ſtyles middling, leaflets linear.

50. Oxalis miniata. *Vermilion Wood Sorrel.*
Jacqu. monogr. 71. t. 35.
Filaments toothleſs, ſtyles very ſhort, leaflets linear.

51. Oxalis verſicolor. *Striped-flowered Wood Sorrel.*
Lin. ſpec. 622. ſyſt. 434. Reich. 2. 390. Jacqu. monogr. 72. t. 36 & 77. f. 4. Thunb. diſſ. n. 19. prodr. cap. 83. Curt. magaz. 155. Smith ic. rar. 7. t. 7.
Filaments toothletted, ſtyles very long, ſtem upright hairy generally ſimple, leaflets linear callous on the under ſide at the tip.

52. Oxalis elongata.
Jacqu. monogr. 73. t. 37.
Filaments toothletted, ſtyles very ſhort, petals emarginate, leaflets linear.

53. Oxalis tenuifolia. *Fine-leaved Wood Sorrel.*
Jacqu. monogr. 74. t. 38.
Filaments toothletted, ſtyles very ſhort, petals quite entire, leaflets linear.

54. Oxalis polyphylla. *Many-leaved Wood Sorrel.*
Jacqu. monogr. 75. t. 39.
O. verſicolor. *Jacqu. collect. 3. 225. ic. rar. vol. 3.*
Filaments gibboſely toothletted, ſtyles middling, leaflets linear.

55. Oxalis cuneata.
Jacqu. monogr. 76. t. 40.
Filaments toothleſs, ſtyles very long, leaflets wedge-ſhaped.

56. Oxalis cuneifolia.
Jacqu. monogr. 77. t. 41.
Filaments toothleſs, ſtyles very ſhort, leaflets wedge-ſhaped.

57. Oxalis glabra. *Smooth Wood Sorrel.*
Lin. ſyſt. 433. Jacqu. monogr. 78. t. 76. f. 3. Thunb. diſſ. n. 17. t. 2. prodr. cap. 83.
Filaments toothletted, ſtyles very long—ſtipe upright ſmooth, leaflets oblong or wedge-ſhaped ſmooth.

58. Oxalis puſilla. *Dwarf Wood Sorrel.*
Thunb. monogr. 79. t. 24.
Filaments toothletted, ſtyles middling, leaflets wedge-ſhaped.

59. Oxalis ambigua. *Doubtful Wood Sorrel.*
Jacqu. monogr. 80. t. 43.
Styles very long, leaflets unſpotted flat, the middle ones wedge-ſhaped, the ſide ones oblong, calycine leaflets equal.

60. Oxalis undulata. *Wave-leaved Wood Sorrel.*
Jacqu. monogr. 81. t. 44.
Styles very long, leaflets unſpotted waved, middle wedge-ſhaped, lateral oblong, one leaflet of the calyx ſpatulate.

61. Oxalis ſuſcata.
Jacqu. monogr. 82. t. 45.
Styles very long, leaflets ſpotted on both ſides, middle wedge-ſhaped lateral oblong.

62. Oxalis glandulofa. *Glandular Wood Sorrel.*
Jacqu. monogr. 83. t. 46.

Styles middling, leaves and calyxes capitately ciliate, middle leaflet wedgeſhaped lateral ones oblong.

63. Oxalis tricolor. *Three-coloured Wood Sorrel.*
Jacqu. monogr. 84. *t.* 47.
β. *Id.* 85. *t.* 48.
Styles middling, cilias ſimple, middle leaflet wedge-ſhaped, lateral ones oblong.

64. Oxalis exaltata.
Jacqu. monogr. 86. *t.* 49.
Styles very ſhort, leaflets duſky-ſpotted, middle wedge-ſhaped lateral oblong, ſcapes upright.

65. Oxalis rubroflava.
Jacqu. monogr. 87. *t.* 50.
Styles very ſhort, leaflets unſpotted, middle wedge-ſhaped lateral oblong, ſcapes upright.

66. Oxalis flaccida.
Jacqu. monogr. 88. *t.* 51.
Styles very ſhort, leaflets unſpotted, middle wedge-ſhaped lateral oblong, ſcapes flaccid.

67. Oxalis variabilis. *Variable Wood Sorrel.*
Jacqu. monogr. 89. *t.* 52.
O. purpurea foliis totis viridibus, limbo albo. *Thunb. diſſ. n.* 8. 1. β.
β. O. variabilis rubra. *Jacqu. monogr.* 90. *t.* 53.
Styles very ſhort, leaflets roundiſh unſpotted very ſlightly emarginate.

68. Oxalis grandiflora. *Great-flowered Wood Sorrel.*
Jacqu. monogr. 91. *t.* 54.
Styles very ſhort, leaflets roundiſh frequently blood-red underneath, ſcarcely emarginate.

69. Oxalis convexula. *Convex-leaved Wood Sorrel.*
Jacqu. monogr. 92. *t.* 55.
Styles middling, filaments toothleſs, leaflets roundiſh convex.]

70. Oxalis purpurea. *Purple Wood Sorrel.*
Lin. ſpec. 621. *ſyſt.* 432. *Reich.* 2. 389. *hort. cliff.* 175. *Jacqu. monogr.* 93. *t.* 56. *Thunb. diſſ. n.* 8. *prodr. cap.* 82. *Knipb. cent.* 3. *n.* 70. *Ehret pict. t.* 10. *f.* 2. *Breyn. cent.* 102. *t.* 46. *Comm. hort.* 1. 41. *t.* 21. (Oxys.)
Styles middling, filaments toothletted, petioles round, leaflets roundiſh unſpotted ciliate.

[71. Oxalis laxula.
Jacqu. monogr. 94. *t.* 57. *Thunb. diſſ. n.* 8. 2. γ.
Styles middling, filaments toothletted, petioles round, leaflets roundiſh often purple underneath.

72. Oxalis breviſcapa.
Jacqu. monogr. 95. *t.* 58.
Styles middling, filaments toothletted, petioles thick compreſſed, leaflets roundiſh.

73. Oxalis rigidula.
Jacqu. monogr. 96. *t.* 59.
Styles very long, leaflets roundiſh unſpotted.

74. Oxalis ſpecioſa. *Handſome Wood Sorrel.*
Jacqu. monogr. 97. *t.* 60. *Thunb. diſſ. n.* 8. 2. α.
Styles very long, leaflets roundiſh, unſpotted above, underneath blood red and dotted with gold.

75. Oxalis ſuggillata.
Jacqu. monogr. 98. *t.* 61.
Styles very long, leaflets roundiſh, when adult livid underneath all over and above at the edges.

76. Oxalis truncatula. *Truncate-leaved Wood Sorrel.*
Jacqu. monogr. 99. *t.* 62.
Styles very long, leaflets roundiſh truncated.

77. Oxalis ſulphurea. *Sulphur-coloured Wood Sorrel.*
Jacqu. monogr. 100. *t.* 63.
Styles very ſhort, filaments toothleſs, calyx ciliate, leaflets obcordate.

78. Oxalis natans. *Floating Wood Sorrel.*
Lin. ſyſt. 432. *Jacqu. monogr.* 101. *t.* 76. *f.* 2. *Thunb. diſſ. n.* 4.
Styles very ſhort, filaments toothleſs, calyx ſmooth at the edges, leaves floating, leaflets obcordate.

79. Oxalis ſtrumoſa.
Jacqu. monogr. 102. *t.* 64.
Styles very ſhort, filaments toothletted equal, leaflets ſpotted on both ſides, middle one obcordate, lateral ones roundiſh.

80. Oxalis luteola.
Jacqu. monogr. 103. *t.* 65.
Styles very ſhort, filaments toothletted equal, leaflets obcordate, unſpotted and ſomewhat villoſe on both ſides.

81. Oxalis lanata. *Woolly Wood Sorrel.*
Lin. ſyſt. 432. *Jacqu. monogr.* 104. *t.* 77. *f.* 2. *Thunb. diſſ. n.* 6. β.
Styles very ſhort, filaments gibbouſly toothletted equal, leaflets obcordate very birſute on both ſides.

82. Oxalis punctata. *Dotted Wood Sorrel.*
Lin. ſyſt. 432. *Jacqu. monogr.* 105. *t.* 66. *Thunb. diſſ. n.* 3. *t.* 1.
Styles very ſhort, filaments toothletted unequal, leaflets underneath coloured and dotted with gold, middle one obcordate, lateral ones roundiſh.

83. Oxalis obtuſa.
Jacqu. monogr. 106. *t.* 79. *f.* 1.
O. lanata. *Thunb. diſſ. n.* 6. α.
Styles middling, filaments toothletted unequal, calycine leaflets rounded-blunt, leaflets obcordate.

84. Oxalis fallax.
Jacqu. monogr. 107. *t.* 67.
Styles middling, filaments toothletted equal, leaflets obcordate.

85. Oxalis marginata.
Jacqu. monogr. 108. *t.* 68.
Styles middling, filaments toothleſs equal, leaflets obcordate.

86. Oxalis pulchella. *Pretty Wood Sorrel.*
Jacqu. monogr. 109. *t.* 69.
Styles very long, filaments toothleſs, leaflets obcordate.

87. Oxalis macrogonya.
Jacqu. monogr. 110. *t.* 70.
Styles very long, filaments toothletted, ſtipe ſubterraneous, leaflets obcordate.]

Styles very long, leaflets very hirſute underneath.

DESCRIPTIONS, *&c.*

The root in this genus is commonly bulbous; in ſome ſpecies only thick and fleſhy; in a few branched: the bulbs conſiſt of fleſhy ſcales, ſometimes cloſely imbricate, ſometimes loote and diverging. In a few the ſubterraneous ſtipe and the terminating fibre of the bulb produce little dog-toothed bulbs, in ſuch abundance as to fill the whole pot to the very bottom, as in *purpurea, cernua, reptatrix.* Sometimes the bulb ſtrikes very deep, as in *tomentoſa*; the original bulb near the ſurface ſtriking a radical fibre downright from its baſe, which puts out from its ſide a new bulb, producing the next year's plant, whilſt the former periſhes: if then the young plant be pulled up, the ſtem under ground is often broken off from the bulb, which has given occaſion to a wrong deſcription of the root. Bulbs which have a hard entire coat moſt eaſily periſh, becauſe perhaps the nucleus is ſuffocated. Sometimes fuſiform, thick and long fibres ſpring in a monſtrous form from the bulbs, as in *glandulofa* and ſome others.

Some of the ſpecies have a proper *Stem* (Caulis), when it bears all the leaves and peduncles alternately, and not in a terminating umbel: this is either branched or quite ſimple, and that for the moſt part inconſtantly. Others have a *Stipe*; the leaves and flowers being aggregate together at the end of the ſtalk; this bears none or very few leaves along it, ſeldom many: this is ſometimes *ſubterraneous* or concealed under ground, when the plant is vulgarly called *ſtemleſs*; ſometimes it is above ground (exſertus), and is upright, reclining or procumbent; in the ſame plant the ſtipe is frequently from an inch to half a foot in height, and ſometimes there is none, as particularly in *polyphylla*. In ſome ſpecies the ſtipe is always ſubterraneous, as in *breviſcape, purpurea*, &c.: in others it is always *exſert*, as in *gracilis, verſicolor, tenuifolia*. Stipes are commonly quite ſimple; ſome however are branched, the branches terminating in umbels, as *incarnata* and *polyphylla*. Hence the diviſion of the ſpecies into *caulefcent* and *ſtipitate*.

The leaves are not perhaps truly ſeſſile in any of the ſpecies; they are ſubſeſſile in a few, but in moſt are petioled. They are ſimple in three ſpecies, binate in four, pinnate in one, digitate in ſix, in the reſt ternate. The petiole in a few ſprings from a widened ſubmembranaceous baſe; but in moſt the baſe itſelf of the petiole forms a ſhort joint, which is eaſily diſtinguiſhed by the ſurrounding ring; in very few it is winged.—The leaflets are generally ſubſeſſile or on very ſhort petioles, very different in their forms, commonly more or leſs dotted, very ſeldom quite ſmooth; in ſome green on both ſides, but in others coloured and frequently very elegantly underneath: almoſt all of them have an acid taſte; whence their names of Oxalis or Oxys, Wood Sorrel, &c.

The partial ſtem bearing the flower is a *peduncle* in the cauleſcent; a *ſcape* in the ſtipitate ſpecies. Each, like the petiole, ariſes at the baſe from a joint; very few ſpecies being without it.—Moſt of them have two little bractes; ſometimes alternate without any joint, ſometimes oppoſite, and then uſually ſpringing from a maniſeſt joint: they are placed at the bottom of the peduncle in ſome ſpecies, about the middle in others, at top or even cloſe under the calyx in others; but always conſtant in the ſame ſpecies. Very few are deſtitute of theſe bractes.

The calyx in moſt of the ſpecies is *ſo ſlightly* united at the baſe, that it is more properly five-leaved than five-parted: in the common ſort (O. Acetoſella) however it is truly one-leafed: the leaflets vary ſo much, even in the ſame flower, in hairineſs, colour and breadth, that they are little to be depended on for ſpecific diſtinctions.

Tournefort, Ray, Rivinus, Ludwig, Magnol, Allioni, Thunberg conſider the corolla as monopetalous; Ruppius and Knauth as pentapetalous; Linnæus takes the middle way, in deſcribing it as cohering ſlightly at the baſe; in the Kew catalogue the corolla is ſaid to conſiſt of five petals ſlightly cohering at the baſe; Dillenius alſo, to the ſpecies he has deſcribed, attributes five petals cohering ſlightly at the claws; Haller likewiſe conſiders the corolla as pentapetalous. Certainly the five baſes of the claws being diſtinct in moſt of the ſpecies, but not in all, indicate the corolla to be pentapetalous: nay there are ſome ſpecies in which the petals are entirely diſtinct, without the leaſt connection; in others the union is ſo very ſlight, that they may be ſeparated without tearing them; in others again they are really connected: this diſtinction therefore is uncertain, but upon the whole the corolla is beſt conſidered as pentapetalous. The figure of the corolla is generally campanulate, with almoſt upright claws, and a ſpreading wide border. A few have the claws very long, all together forming a cylinder, with the border ſpreading out very much; this ſort of corolla may be named *caryophylleous* from its reſemblance to that of a Pink. The colour of the corolla is white, yellow, purple or red, except in very few ſpecies, varying only in intenſity.

The filaments are commonly united into a cylinder at the baſe, and therefore are monadelphous: in a very few they are quite ſeparate, they are all placed in the ſame circle at the baſe, but as they riſe, five of them alternately tend inwards, and are called interior; the other five, being more upright, are ſaid to be exterior. In moſt ſpecies the interior filaments (the exterior never) put forth from the thickened back at bottom a very evident tooth, in others only an obtuſe bump, theſe are ſaid to be *toothletted*; thoſe which have none of this proceſs are called *toothleſs*. The interior filaments are always longer than the exterior, and are themſelves ſometimes equal, ſometimes unequal in height. The exterior ones are very rarely unequal. The filaments are either ſmooth or hairy; and the hairs are either ſimple or capitate. The hairineſs or ſmoothneſs is not always the ſame in the filaments of each order; nor do the toothlets always follow the hairineſs of the filaments, and when they are hairy, the hairs are only in front. The anthers are yellow, ſeldom white, incumbent for the moſt part, but in a few ſpecies erect.

The germ is five-cornered, oblong or ovate, ſomewhat hairy eſpecially at the top, ſeldom wholly ſmooth: it is either entirely of a pale green colour, or has a ſingle row of calluſes or orange-coloured dots on each ſide at the corners. Styles ſeldom ſmooth: ſometimes longer than the interior filaments, or *very long*; ſometimes ſhorter than theſe, but longer than the exterior filaments, or of a *middling* length; ſometimes ſhorter than the latter, denominated *very ſhort*; or preciſely *equal* to the interior filaments, which is very rare. The ſtigmas are pencilled almoſt in all; in a very few capitate. This proportion of the ſtyles to the ſtamens, together with the equality or inequality of the filaments, and the preſence or want of the toothlets, being conſtant, are circumſtances fit to make uſe of in forming *diagnoſes* or ſpecific differences.

The fruit in many of the ſpecies is unknown, but in thoſe that are known, the capſule is more or leſs quinquangular ſeldom five-winged, cylindric or ovate, generally villoſe, five-celled and longitudinally five-valved. The ſeeds in ſome very few, in others many in a longitudinal row lying over each other, roundiſh, ſomewhat compreſſed, and tranſverſely wrinkled. Each ſeed is incloſed in a white coriaceous pellucid and very ſhining pellicle, which is a ſort of aril. This aril becomes dry in the ripe ſeed, and then ſeparates with a conſiderable elaſtic force into two cohering valves,

sets the seed free, and together with it is violently cast forth at the opening angles of the capsule. The capsules then dry and contract. The aril retains the wrinkles of the seed impressed upon it.

Linneus first gave the name of *Oxalis* to this genus, in his hortus Cliffortianus, and the name has been adopted by most modern botanists. The *Oxalis* of Pliny however seems to be a species of Rumex, Lapathum or Dock, and probably *Rumex Acetosella* or Common Sorrel. The older botanists, and Haller, Scopoli and Allioni among the moderns, name the genus, with more judgment *Oxys*, Pliny having described the Oxys as having ternate leaves: he probably means our *Oxalis cornicülata*, which is a native of Italy. In deference however to Linneus and his followers, the name of *Oxalis* is here adopted [a].

Of the ninety-six species here set down from Jacquin's fine work on this genus, two only are natives of Europe, one of the East Indies, twelve of America, and all the rest of the Cape of Good Hope, that inexhaustible treasury of beautiful plants. Jacquin is here servilely followed, that illustrious author having bestowed great pains in ascertaining and describing the species; some of which however can scarcely be allowed to be any thing more than varieties.

1. Root branched. Stem a foot and half high, round, branched, the thickness of a pigeon's quill; when old brownish, smooth, when young pubescent. Branches the same. Leaves alternate, approximating at the ends of the branches, ternate. Petiole not jointed at the base, slender, hirsute, about an inch in length. Leaves obovate or oval, rounded, villose at the edge, dotted on both sides and rough with very short hairs, petioled; the lateral ones generally emarginate; the middle one larger, on a longer petiole, and for the most part quite entire. Peduncles not jointed at the base, axillary, solitary, filiform, hirsute, the length of the leaves, twice bifid at top, five-flowered; divisions very short and each supported by a little twin linear hirsute bractæ: pedicels jointed at bottom. Calycine leaflets lanceolate, acute, villose at the edge, very hirsute, upright. Corolla three times as long as the calyx, bell-shaped, spreading very much at top, rounded, yellow. Filaments connate at the base: interior toothless, equal, hirsute with simple hairs: exterior smooth. Anthers incumbent. Styles smooth. Native of the Caracas in South America.

2. Root branched. Stem round, villose, a foot and half high, the thickness of a pigeon's quill. Branches hirsute. Leaves alternate, or several together from the same point at intervals, ternate. Petiole not jointed at the base, slender, hirsute, spreading, about an inch and half in length. Leaflets subsessile, subovate-rhombed, bluntish, quite entire, villose at the edge, and minutely villose on both sides; the middle one longer, about an inch in length. Peduncles not jointed at the base, filiform, from the axils of the aggregate leaves, hirsute, umbelliferous, with an involucre of two opposite, linear, hirsute leaflets. Pedicels in pairs or threes, hirsute, commonly simple and one-flowered, more seldom bifid and two-flowered, with a little bractæ at the division. Calycine leaflets lanceolate, acute, villose at the edge, hirsute, erect. Corolla three times as long as the calyx, bell-shaped, spreading very much at top, rounded. Filaments connate at the base: interior toothless, equal, hirsute with simple hairs: exterior smooth. Anthers incumbent. Styles hirsute with simple hairs.—Native of the Caracas in South America [a].

3. Root branched. Stem round, a foot high. Leaves alternate, ternate. Petiole round, spreading, two or three inches long. Leaflets bluntish, quite entire, the middle one longer, often more than an inch in length, petioled. Peduncles axillary, solitary, spreading, about the length of the leaves. Pedicels three or four, simple, short. Calycine leaflets lanceolate, acute. Corolla almost three times as long as the calyx, bell-shaped, yellow [b].

[a] Jacquin, monogr. introd. [b] Jacquin.

[b] Jacquin from Plumier.

Jacquin has changed Linneus's name of *frutescens*, this species having the appearance perhaps of becoming something shrubby at bottom only in common with the two former and the next succeeding species; but it does not seem that any Oxalis is really frutescent.

Native of the Caribbee islands and Guiana.] Discovered by Plumier; and afterwards found growing plentifully at La Vera Cruz by Dr. Houstoun, who sent it to England. Mr. Miller says, it rises with a shrubby stalk a foot and half high, sending out several slender branches. Leaves in pairs or threes, on short petioles. Peduncles near two inches long; each sustaining four or five yellow flowers, with the petals not much longer than the calyx: each flower being on a crooked pedicel hangs down.

4. [Root branched annual. Stem somewhat villose, round, the thickness of a reed at the base, dusky at bottom, a foot and half high, putting forth many alternate branches below. Leaves alternate, ternate. Petiole not jointed at the base, half round, slightly grooved in front, somewhat hirsute, from an inch to two inches in length. Leaflets oblong or ovate, bluntish, quite entire, smooth above, somewhat villose underneath, appearing dotted when examined by a glass or held up to the light, petioled, an inch long, the middle leaflet a little larger and on a longer petiole. Peduncles not jointed at the base, axillary, solitary, generally shorter than the petioles, racemed with a solitary flower at the division; pedicels very short with very minute bractæ. Calycine leaflets lanceolate, acuminate, smooth, green, upright. Corolla twice as long as the calyx, spreading very much at top, rounded, smooth, flesh-coloured. Filaments united at the base: interior toothletted, equal, hirsute with capitate hairs, the toothlets smooth; exterior smooth. Anthers incumbent, yellow. Styles the length of the interior filaments, hirsute with simple hairs. Stigmas capitate not pencilled. Capsule ovate, pentagon-winged, acute. Seeds in each cell commonly two, ovate, acute, wrinkled, brown. It flowers in the stove from may to october.—Native of the Caracas, and Guiana [a].]

Mr. Miller says, it grows naturally in the Brazils; plants having come up in plenty, in a tub of earth which came thence. According to him, it seldom rises more than three or four inches high: the leaflets are large and hairy, on long foot-stalks: the flowers rise immediately from the root, on scapes the same length with the leaves, bifid, and supporting two pretty large red flowers. Capsules oblong, filled with brown seeds.

[Jacquin refers Feuillée's synonym, attributed by Murray to this species, to the next.

5. Root branched, annual. Stem half a foot high, the thickness of a reed. Leaves alternate, ternate. Petiole two inches long, spreading. Leaflets sessile, scarcely half an inch long. Peduncles axillary, solitary, erect: pedicels shortish, one-flowered. Calycine leaflets lanceolate, acute, erect. Corolla almost three times as long as the calyx, bell-shaped: claws upright: border obovate, rounded, rose-coloured with six red lines from the base to the middle.—Native of Chili, in moist places [a].

6. Root perennial, turbinate, putting forth capillary fibrils from the side, near an inch thick at top, ending in a sharp point at bottom, fleshy, dusky ash-coloured. Stem round, somewhat scaly, half an inch high, putting forth from the top several leaves and several branches or stems, erect, round, slender, white-villose, pale green, about nine inches long. Leaves alternate, ternate. Petioles about an inch and half in length, spreading. Leaflets sessile, half an inch long. Peduncles axillary, solitary, two-flowered or one-flowered, the length of the leaves; with little bractæ to the pedicels opposite and acute. Calycine leaflets lanceolate, acute, erect. Corolla many times longer than the calyx, very wide, rounded, yellow. Capsule membranaceous, five-celled; with many small seeds.

Native of Paraguay, in the vast plain to the north-

[a] Jacqu. monogr. [a] Jacqu. from Feuillée.

ward

ward of the river de la Plata. Observed by Feuillée with the preceding and two next species [a].

Jacquin gave this species its trivial name from the shape of the root, like a top: from *κονος*, *turbo*.

7. Root annual, fusiform, putting forth many fibrils, half an inch thick at top, pale green. Stem round, two feet high, branched, half an inch thick at the base, pale green, full of an acid juice. Leaves alternate, ternate. Petiole jointed at the base, round, spreading a little or almost upright, some inches in length. Leaflets sessile. Peduncles axillary, solitary, almost upright, about the same length with the leaves. Pedicels about eight, before flowering drooping, but whilst in flower upright. Calycine leaflets lanceolate, acute. Corolla three times as long as the calyx, bell-shaped, ten lines in diameter, yellow with purple streaks on the inside; borders crenate.

Native of Peru. It seems to be wholly smooth. About Lima it is generally cultivated in gardens, and is used as Sorrel [b].

8. Root annual, branched, fibrous. Stem round, branched, half a foot high, villose. Leaves scattered, ternate. Petiole villose, about an inch and half in length. Leaflets sessile, smooth above, underneath and at the edges villose, slightly tinged with red at the edge, especially at the back, scarcely half an inch long. Peduncles axillary, with appressed hairs. Leaflets of the involucre lanceolate, acute, small. Pedicels commonly in pairs, sometimes three or four together, slender, before flowering drooping, then erect, when fruiting reflex. Calycine leaflets lanceolate, acute, erect. Corolla three times as long as the calyx, yellow; border obovate, emarginate, spreading very much. Capsule narrow-conical, five-grooved, villose, erect, almost an inch long. Seeds roundish, white, shining.

Native of Carolina. It flowers here in june and july [c]. Cultivated in Sherard's garden at Eltham before 1732.

9. Root perennial, creeping, round, putting out capillary fibres at the knots, branched. Stems from the root as it creeps along several, roundish, slender, somewhat villose, purplish, finally branched, half a foot high and more, upright but being weak often lying down, annual. Leaves alternate, a few sometimes opposite, ternate. Petiole springing from a joint margined in front, round, villose, spreading, from two to four inches long, flaccid. Leaflets subpetioled, somewhat hirsute on both sides with decumbent hairs and green, ciliate, scarcely half an inch long. Peduncles axillary, jointed at the base, round, villose, upright, about the same length with the leaves, having from two to seven flowers in an umbel, with a pedicel often branched: leaflets of the involucre several, ciliate and somewhat hirsute. Calycine leaflets lanceolate, sharpish, somewhat hirsute, ciliate, pale green, erect. Corolla twice or thrice as long as the calyx, subcampanulate, yellow: claws upright, border obovate, very obscurely emarginate and very spreading. Filaments connate in a cylinder; interior toothless, equal, having a very few capitate hairs at top, in other parts smooth: outer smooth. Anthers oblong, incumbent, yellow. Germ oblong, hirsute, pale green. Styles almost equal, hirsute with simple hairs. Capsule columnar, sharpish, hirsute, five-cornered [d].

Swartz observes, that it varies with a stiffer and weaker stem, upright or declining, so that it is scarcely any thing more than a variety of *O. corniculata*.

Mr. Salisbury describes his *O. ambigua* as having a creeping stem, ternate leaves, on half-round petioles without stipules, emarginate leaflets, the petals obovate quite entire, styles the height of the longer filaments and spreading.

Mr. Salisbury remarks, that though the primary stems in some degree answer to the definition which Linnæus has given of the term *fruticus*, yet the branches which break out near the root are constantly creeping; there is however an obvious difference to the eye between this and the following.—I have not distinguished it in a genus perhaps already overloaded with species.

Browne recommends it as a pleasant cooler and diuretic, and says that it was formerly administered in inflammatory cases, but has been little used since the more agreeable acid fruit-trees have been so much cultivated in the West Indies.

Native of North America, Jamaica and Piedmont. Cultivated in the botanic garden at Oxford in 1658. It flowers from june to october [e] Mr. Miller remarks, that wherever this plant has been suffered to ripen its seeds, it has become a common weed.

10. [Root branched, fibrous, brownish, annual. Stems several, wholly prostrate, rooting, branched, slender, round, villose, often tinged with purple, growing to half a foot in height or more. Leaves alternate, collected in a small number at the rooting parts of the stems, ternate. Petiole arising from a joint which has two rims in front, round, slender, villose, purplish, almost upright, from an inch to two inches in length. Leaflets subsessile, obcordate, somewhat villose on both sides, and at the edge, dusky green. Peduncles axillary, or on the shorter branches terminating, very shortly jointed at the base, round, somewhat villose, upright, half an inch long, generally two-flowered in a sort of umbel, with an involucre of two or three lanceolate, acute, villose leaflets. Calycine leaflets lanceolate, blunt, villose, ciliate, erect, pale green. Corolla twice as long as the calyx, subcampanulate, yellow: claws erect: borders obovate, blunt, spreading very much. Filaments connected at bottom: interior toothless, equal, having a very few capitate hairs at top, the other parts smooth; exterior smooth. Anthers oblong, incumbent, yellow. Germ oblong, very minutely villose, pale green. Styles almost equal, hirsute with simple hairs. Capsule columnar, acute, somewhat villose, five-cornered with the corners waved [f].]

According to Mr. Miller, the root is long and slender, the trailing stalks spread out eight or nine inches wide on every side, dividing into small branches, the leaves are on pretty long foot-stalks, and the leaflets are more deeply emarginated than in *O. acetosella*. The capsules are near an inch long. [Seeds brown, scored transversely, inclosed in a semitransparent aril or seed-coat, which being pressed, opens with a jerk, and throws out the seed to some distance [g].

Jacquin is of opinion that the *O. corniculata* of Pollich and other Germans is rather his *O. stricta*, which he affirms to be always upright, except when it is beat down by the wind or any accident; whereas the former is always procumbent, the very extremities of the stems and branches being close to the ground, like the runners of the Strawberry; the short flowering-branches only being upright: the stem also creeps, but not the root, which is annual: whereas in *stricta* the root is perennial, and it is that which creeps, not the stem. Retzius indeed affirms, that O. corniculata, protected from frost, is perennial; but that it always continues to be procumbent.

Mr. Salisbury has altered the trivial name to *pusilla*, because it is of much dwarfer growth than the preceding, and the old epithet is applicable to the whole genus. He describes the stem as creeping, the petioles as roundish, and stipuled at the base, with emarginate leaflets; the segments of the corolla obcuneiform, gnawn a little at the tip; and the styles scarcely the height of the longer filaments and subtigiate.

Native of Spain, Italy, Sicily, Greece, Austria, Switzerland, England, Japan, China, Cochinchina.—Cultivated in 1656, by Mr. John Tradescant, Junior [h]. It was not then known to be a native of England, and perhaps it may have established itself since that time in the mild climate of Devonshire; for it increases very abundantly and with great facility. It is said to have been first discovered here by Mr. J. Turner in the neighbourhood of Exeter. In 1781 it was found near Dawlish in Devonshire, and since that in several other places of the same county.

[a] Jacqu. from Feuill. [b] Idem. [c] Jacqu. from Dillenius. [d] Jacqu. monogr. [e] Hort. kew. [f] Jacquin. [g] Hollifex in Withering. [h] Hort. kew.

Mr. Salisbury remarks, that it is a proof of the mildness of the climate there, that this and other southern plants occur in it, as *Pinguicula lusitanica*, *Sibthorpia europæa*, *Lobelia urens*, and *Erica vagans*[a]. O. corniculata flowers from may to october.

11. Root fibrous, slender, branched. Stems radical, several, herbaceous, filiform, leafy, villose, purplish, some inches in length; branchlets alternate, like the stem. Leaves alternate, ternate. Petiole jointed and widening at the base, half round, villose, green, almost upright, half an inch or more. Leaflets obcordate, sessile, ciliate, smooth above, but having a very few villose hairs underneath, very small. Peduncles axillary, jointed at the base, one-flowered or two-flowered, round, villose, slender, almost upright, green: with a pair of little jointing villose bractes about the middle. Calycine leaflets lanceolate, acute, somewhat hirsute, thinly ciliate, upright. Corolla three times as long as the calyx, bell-shaped: claws upright, pale: borders obovate, rounded, spreading very much, yellow. Filaments connate at the base, smooth: interior toothless, equal. Anthers oblong, incumbent, yellow. Germ linear, hirsute. Styles hirsute with simple hairs. Stigma obscurely pencilled.

Native of the Cape of Good Hope, Madagascar, and Ceylon[b].

12. Root perennial, round, an inch in diameter, about eight inches long, having several heads, divided below into branching legs, full of clefts, covered with a double bark, the outer very thin, brownish ash-coloured, the inner two lines in thickness, red, watery, acrid; the substance of it is white, watery, acrid, having red fibres in it running from the centre to the circumference. Leaves radical, several. Petioles almost upright, three inches long. Leaflets subsessile, obcordate, scarcely half an inch in length, bright green above, beautiful violet underneath. Scapes almost upright, bearing several flowers in umbels, and the same length with the leaves. Calycine leaflets lanceolate, acute, erect. Corolla three times as long as the calyx, bell-shaped, yellow, marked below with three red lines on each petal.

Native of Peru, on mountains. This species is singular for the great size of the root, whence its trivial name. The heads of it resemble so many sufruticose stems[c].

13. Bulb deep in the ground. Stipe standing out, villose, having one or two scales, about an inch in length, terminating in an umbel of leaves and scapes. Leaves several. Petiole from a wider base, but not jointed, rough-haired, about an inch in length. Leaflets subsessile, obcordate, greater in breadth than length, a little ciliate, above green with a circle of red, and rough with white hairs, tomentose underneath, purple or silvered, or silvery-purple. Scapes several, rough-haired, umbelliferous, erect, twice as long as the leaves. Peduncles from two to five, one-flowered, the middle ones shorter, drooping, each supported at the origin with two ovate, rough-haired little bractes. Calycine leaflets lanceolate, acute, rough-haired, ciliate. Corolla twice as long as the calyx, yellow. Filaments so very slightly connate at the base as to be almost free, smooth: interior toothletted, equal. Anthers incumbent. Germ long, hirsute. Styles hirsute with simple hairs.—Native of the Cape of Good Hope[d].

14. Bulb roundish-ovate, covered with a black coat, the size of a hazel nut or less, very prolific, consisting of whitish fleshy scales, and having one or two red lines running through them. Stipes several, from the base of the bulb between the scales, subterraneous, round, slender, smooth, white, destitute of scales, each ending in a single leaf or scape. Leaves several. Petiole not jointed, round, thinly hairy, green, frequently purple at bottom, almost upright, weak, from three to six inches in length. Leaflets on very short petioles, very widely obcordate, somewhat villose at the edge, on both sides smoothish, dotted and green, three quarters of an inch in length. Scapes similar to the petioles, simply umbelliferous, or first bifid with a one-flowered peduncle in the division, and then umbelled on both sides. Involucre one-leafed and bifid; segments lanceolate, acute, opposite, smooth, rose-coloured. Peduncles from three to nine, jointed at the base, round, somewhat hairy, half an inch long or more; with little bractes at bottom almost opposite and somewhat villose. Calycine leaflets lanceolate, sharpish, upright, ciliate, somewhat hirsute, pale green, having two, sometimes, but seldom, only one oblong, orange-coloured callus. Corolla three times as long as the calyx, bell-shaped; claws yellowish; borders obovate, rounded, violet-purple, striated, spreading very much. Filaments united at the base: interior gibbosely toothletted equal, very hirsute with simple hairs: outer smooth. Anthers oblong, incumbent, whitish. Germ oblong, pale green, hirsute. Styles somewhat hirsute with simple hairs.—The bulb sometimes produces fleshy roots, the thickness of a finger. The stipes may be considered as nothing but the lower part of the petioles and scapes, and then this species has no stipe.

Native of Virginia[e]. Introduced in 1772, by Samuel Martin, M. D. It flowers in may and june[f]; Jacquin says, the whole summer.

15. Bulb ovate-triangular, even. Stipe subterraneous, terminated by an umbel of leaves and scapes. Leaves several. Petiole jointed at the base, channelled, smooth, from two to three inches in length. Leaflets obcordate, sessile, green above, bright purple underneath, a third part of an inch in length; lobes oblong, rounded. Scapes several, smooth, erect, slender, half a foot in length, umbelliferous. Leaflets of the involucre few, acute, minute, smooth. Peduncles from two to four, one-flowered, somewhat villose, erect, about an inch in length. Calycine leaflets lanceolate-oblong, sharpish, striated, smooth, ciliated a little towards the tip, green with red edges, and having a yellow callus underneath at the tip. Corolla three times as long as the calyx: borders oblong, blunt, crenulate, spreading, blue or flesh-coloured. Filaments connate at the base: interior gibbosely toothletted, unequal, hirsute with simple hairs, but the toothlets are smooth: exterior equal, hirsute as well as the others. Anthers incumbent, yellow. Styles hirsute.

Native of the Cape of Good Hope[g]. The next species is considered as the *caprina*, in the generality of the European gardens, and is perhaps the caprina of Linneus; but this is the *caprina* of Thunberg and Jacquin.

16. Bulb acuminate-ovate, smooth, covered with a brown coat, the largest nine lines in length. Stipe standing out, sometimes only a very little, sometimes an inch or two, often procumbent, round, the thickness of a pigeon's quill, smooth, having a few scales, terminated by an umbel of leaves and flowers; the longer one putting forth also other umbels that are leafy, and at the same time bulbiferous: then without interruption it proceeds from the bulb, penetrates the ground in various directions, and forms either a radical filiform fibre, or a capillary one, some inches long, with fibrils, and generating little bulbs its whole length. Leaves several. Petiole jointed at the base, round, green, almost upright, from three to seven inches long. Leaflets subsessile, obcordate, wider than they are long, often slightly two-lobed, unspotted, from half to three quarters of an inch in length. Scapes few, jointed at the base, round, green, upright, often even a foot high, umbelliferous. Leaflets of the involucre several, lanceolate-linear, acute, short. Peduncles several, as far as seventeen, round, about half an inch long, somewhat villose. Calycine leaflets lanceolate, sharpish, upright, thinly hirsute, green with white edges. Corolla five times as long as the calyx, bell-shaped: claws upright, pale yellow: borders very wide, obovate, rounded, spreading very much, yellow. Filaments connate at the base: interior toothletted, smooth: exterior smooth.

Anthers

Anthers oblong, incumbent. Germ pale greeniſh yellow, hirſute. Styles hirſute with ſimple hairs.

Native of the Cape of Good Hope. Thunberg gave it the name of *cernua* from its drooping flowers[a].

17. Bulb oblong, half an inch long, covered with a brown ſtriated coat. Stipe under ground for an inch in length, then riſing above ground from one to four inches, round, ſmoothiſh, browniſh purple, more ſlender than a pigeon's quill, having a few ſcales, commonly leafleſs, except that it has now and then a ſingle leaf at top, almoſt upright or declining, terminated by an umbel of leaves and flowers. Leaves ſeveral, upright and ſpreading a little. Petiole jointed at the baſe, obſcurely hirſute when examined with a glaſs, from two to three inches in length. Leaflets ſubpetioled, two-lobed-obcordate, dotted on both ſides, above ſmooth and green, not ciliate at the edge, beneath of an elegant and very ſhining violet colour, a little hirſute when viewed with a magnifier, half an inch wide, and not ſo long. Scapes few, jointed at the baſe, one-flowered, round, a little hirſute, almoſt upright, a little longer than the leaves, with a pair of little bractes at the joint above the middle. Calycine leaflets oblong, ſharpiſh, green with red edges, hirſute there and on the back with capitate and ſimple hairs mixed, ſome but not all gaſhed above or below with a toothlet or two, marked below the tip with two oblong orange-coloured calluſes, erect. Corolla four times as long as the calyx, of a violet purple colour, more pale on the outſide, bell-ſhaped, ſpreading very much and wide at the top. Filaments connate at the baſe: interior toothletted, equal, hirſute with ſimple and capitate hairs, and having a ſmooth toothlet: exterior ſmooth. Anthers incumbent, yellow. Styles hirſute with capitate and ſimple hairs.

Native of the Cape of Good Hope. It flowers here in november[b].

18. Bulb ovate, half an inch long, covered with a brown ſtriated coat. Stipe partly ſubterraneous and from one to three inches long; partly ſtanding out two or three inches, round, nearly the thickneſs of a pigeon's quill, ſmooth, leafleſs, upright, terminating in an umbel of many leaves and fewer ſcapes, then elongated above this, and ending in another leafy umbel. Leaves ſeveral, ſpreading. Petiole jointed at the baſe, round, grooved in front, ſlender, ſparingly villoſe, livid with redneſs, about two inches long. Leaflets on very ſhort petioles, obcordate, almoſt half-lobed, dotted on both ſides, ſcarcely half an inch in length and breadth, above ſmooth and livid green, underneath of a very elegant and deep livid violet-colour, ſomewhat hirſute with very few white decumbent hairs. Scapes very few, frequently only one, very ſhortly jointed at the baſe, umbellately two-flowered, round, obſcurely villoſe, thicker and longer than the petioles, livid, ſpreading, with a pair of lanceolate, acute little bractes under the umbel. Pedicels an inch long, not jointed, ſomewhat villoſe, ſtraight, purpliſh, with two very minute oppoſite little bractes at the baſe of each. Calycine leaflets lanceolate, bluntiſh, green with purple edges, having both ſimple and capitate hairs at the edges and on the back, marked below the tip underneath with four oblong orange-coloured lines. Corolla four times as long as the calyx: claws erect, yelloweſh: borders rounded-wedge-ſhaped, ſpreading very much, fleſh-coloured, with the back on one ſide ſomewhat villoſe. Filaments connate at the baſe: interior toothletted, equal, hirſute with both ſimple and capitate hairs, and a few hairs to the toothlets: exterior ſmooth. Anthers oblong, incumbent, yellow. Germ pale green, ſomewhat hirſute at top. Styles hirſute with hairs of both ſorts.

Native of the Cape of Good Hope. It flowers with us in october and november[c].

19. Stipe ſubterraneous, terminating in an umbel of leaves and ſcapes. Leaves very many. Petiole linear, compreſſed-winged, unequal, ciliate, about an inch in length. Leaflets ſubſeſſile, obcordate, ciliate, ſmooth and green above, hirſute and whitiſh underneath, a third part of an inch in length. Scapes ſeveral, round, hirſute, *two*-flowered, erect, two inches long. Leaflets of the involucre two, oppoſite, lanceolate, acute, hirſute. Peduncles ſcarcely half an inch in length, hirſute, erect. Calycine leaflets lanceolate, acute, erect, hirſute. Corolla four times as long as the calyx, bell-ſhaped, yellow. Filaments connate at the baſe, ſmooth: interior toothletted, equal. Anthers oblong, incumbent. Germ hirſute, the length of the ſtamens. Styles hirſute with ſimple hairs.—Native of the Cape of Good Hope[d].

20. Bulb oblong. Stipe ſubterraneous, terminating in an umbel of leaves and ſcapes. Leaves very many. Petiole two or three inches long. Leaflets ſix or five, lanceolate, ſmooth, thick, ſucculent, quite entire, ſeſſile, green, diſpoſed in a ring. Scapes ſeveral, a ſpan in length, ſmooth, upright, umbelliferous. Peduncles ſeveral, drooping till the flowers open, and then upright. Calycine leaflets lanceolate, acute, erect. Corolla five times as long as the calyx, bell-ſhaped, yellow.

Native of the Cape of Good Hope[e]. Linnæus unites it with *cernua*, from which it is very different in the leaves[f].

21. Root fibrous, brown. Stipe ſtanding out, round, about the thickneſs of a pigeon's quill, from half an inch to ſix inches in height, obſcurely jointed below, variegated with red or brown and green, filled with a white pith, terminating in a cloſe umbel of leaves and flowers. Leaves numerous, abruptly pinnate, ſpreading. Rib hirſute, often ſmooth at top, from two to five inches long. Leaflets from eight to fifteen on both ſides, ſeſſile, oppoſite, oblong, very blunt with a ſmall innocuous point, moſt of them very ſmooth, but ſome thinly hairy underneath, quite entire, from two to four inches long, the younger ones yelloweſh green, the older glaucous above and purple beneath. Scapes very many, ſomewhat villoſe, almoſt upright, a little longer than the leaves, umbelliferous. Leaflets of the involucre ſeveral, awl-ſhaped, villoſe. Peduncles for the moſt part ſeven or eight, one-flowered, ſhort. Calycine leaflets lanceolate-acuminate, villoſe, upright. Corolla yellow. Filaments diſtinct, not connate, awl-ſhaped, toothleſs, hirſute with ſimple hairs, upright, five alternately three times as long as the others. Anthers incumbent. Germ ovate, ſomewhat hirſute at top. Styles of middling length, ſmooth. Stigmas bifid, not pencilled. The leaves contract on the ſlighteſt touch[g]: hence the trivial name. Capſule pentagon-ovate, five-celled, five-valved, opening at the angles. It is a very beautiful plant[h].

Native of Malabar, Ceylon, the Molucca iſlands, and other parts of the Eaſt Indies. In China and Cochinchina.

22. Bulb ovate, covered with a ferruginous ſhining coat, the ſize of a hazel nut. Stem round, hirſute, purple, ſlender, ſomewhat branched, from ſix to nine inches high, almoſt upright. Leaves ſubſeſſile, ſcattered, approximating, ſpreading very much, ternate. Leaflets ſubſeſſile, linear-wedge-ſhaped, blunt, quite entire or very ſlightly emarginate, dotted on both ſides, ciliate at the edges with minute villoſe hairs, ſmooth above, ſomewhat hirſute underneath with pale orange calluſes ſcattered without order, half an inch long. Peduncles not jointed at the baſe, axillary, ſolitary, round, villoſe, almoſt upright, alternate, two inches long, with little bractes generally alternate a little below the calyx. Calycine leaflets lanceolate, acute, ciliate, ſomewhat hirſute, pale green, upright. Claws of the corolla yellow within, dirty yellow on the outſide, villoſe when examined by a glaſs, upright, embracing each other ſo as to form a cylinder near an inch in length: borders oblong, blunt, ſpreading very much, red-purple, paler underneath, with one ſide yelloweſh, almoſt three times ſhorter than the claws. Filaments united at the baſe: interior toothleſs, equal. Anthers oblong, twin, erect, yellow. Germ oblong, villoſe at top, pale greeniſh yellow, callous. Styles remarkable for their length; whence the trivial name: all theſe parts are hirſute with ſimple hairs.

[a] Jacqu. from Thunb. [b] Jacquin. [c] Idem. [d] Jacqu. from Burm. [e] Idem. [f] Loureiro.

Native of the Cape of Good Hope. It flowers in Europe in october[1].

23. Bulb roundiſh, covered with a browniſh coat, the ſize of a hazel nut or larger. Stem round, very hirſute, almoſt all leafy, ſometimes but ſeldom having a ſingle branchlet, half a foot high, almoſt upright, weak, about half the thickneſs of a pigeon's quill. Leaves alternate, ſubſeſſile, ſpreading very much; ternate. Leaflets linear-lanceolate, ſharpiſh, quite entire, green on both ſides and dotted, ciliate with villoſe hairs at the edges, ſmooth above, underneath hirſute and without any conſpicuous calluſes, ſcarcely half an inch long. Peduncles not jointed at the baſe, axillary, ſolitary, round, hirſute, almoſt of the ſame thickneſs with the ſtem, two inches long, almoſt upright, alternate, pale, with little bractes approximately alternate below the calyx. Calycine leaflets lanceolate, ſharpiſh, ciliate, villoſe, pale green with blood-red edges, erect. Claws of the corolla yellow within, dirty without and villoſe, erect, forming a cylindric tube an inch long: borders obovate, ſharpiſh, ſpreading very much, leſs than half the length of the claws, red-purple within, a little paler on the outſide, with one ſide dirty yellow and ſomewhat villoſe. Filaments united, capillary, ſomewhat hirſute with ſimple hairs: interior toothleſs, unequal, very long: exterior alſo generally unequal. Anthers incumbent, yellow. Styles ſmooth.

Native of the Cape of Good Hope. It flowers in Europe in october and november[2].

24. Bulb roundiſh or ovate, from the ſize of a pea to that of a hazel nut, with the ſcales a little looſe, the outer ones brown, the inner whitiſh dotted with red. Stem round, villoſe, half the thickneſs of a pigeon's quill, upright, half a foot high, ſcaly at the baſe, either quite ſimple or branched from the axils of the leaves. Leaves alternate, on very ſhort petioles, approximating, ternate. Leaflets ſubſeſſile, wedge-ſhaped, rounded, emarginate, ciliated with villoſe hairs, ſmooth and dotted above, underneath hirſute with many ſcattered calluſes not very conſpicuous, half an inch long. Peduncles not jointed at the baſe, axillary, ſolitary, erect, alternate, villoſe, pale green, half an inch long, with alternate, approximating bractes below the calyx. Calycine leaflets oblong, ſharpiſh, erect, ciliate, hirſute, green with two orange-coloured lines deſcending from the tip. Claws of the corolla three times as long as the calyx, erect, yellow within, of a pale dirty yellow and villoſe on the outſide, forming a cylindric tube: borders obovate, rounded, ſpreading very much, about half the length of the claws, purpliſh-roſe-colour within, paler on the outſide, and a little villoſe on one ſide. Filaments connate, hirſute with a few ſhort villoſe hairs: the interior ones toothleſs and equal. Anthers incumbent, yellow. Germ oblong, pale greeniſh yellow with orange ſtreaks, hirſute at top. Styles ſomewhat villoſe.

Native of the Cape of Good Hope. In Europe it flowers in ſeptember and october[3].

25. Bulb roundiſh, covered with a brown coat, larger than a hazel nut. Stem round, the thickneſs of a pigeon's quill, extremely villoſe, browniſh, only at bottom ſcaly and leafleſs, weak, about a foot high, upright for ſome inches and then more or leſs reclining, from moſt of the leaves below the flowers increaſed by axillary erect branchlets, that grow to half a foot in length, but ſcarcely ever bear flowers. Leaves alternate, approximating, on very ſhort petioles, ternate. Leaflets ſubſeſſile, wedge-ſhaped, blunt, on account of their reflex tip ſeeming to be emarginate, green on both ſides, and appearing dotted by a magnifier, ciliated with villoſe hairs at the edge, ſmooth above, beneath ſomewhat hirſute and having very many ſcattered calluſes of a dirty orange colour, hardly viſible without a glaſs, ſcarcely half an inch in length. Peduncles not jointed at the baſe, axillary, ſolitary, round, villoſe, the length of the leaves, erect, with oppoſite bractes immediately under the calyx. Calycine leaflets lanceolate, acute, ciliate, villoſe, pale green, erect. Corolla red-violet: claws erect, villoſe on the outſide, forming a cylindric tube an inch in length: borders obovate, rounded, ſmooth, ſpreading very much, one third only of the length of the claws. Filaments connate, ſmooth: interior toothleſs, unequal. Anthers oblong, bifid at the baſe, erect, yellow. Germ ſlender, ſmooth, pale greeniſh yellow, callous. Styles hirſute with ſimple hairs thinly ſet.

Native of the Cape of Good Hope. It flowers in Europe in october and november[4].

26. Bulb roundiſh, covered with a brown coat, the ſize of a hazel nut. Stem round, ſlender, ſmooth at bottom, the reſt villoſe, about eight inches in length, purpliſh brown, weak, flaccid, hence it is ſometimes almoſt upright, ſometimes decumbent or aſcending, putting forth from the axils branchlets that ſeldom flower. Leaves alternate, on very ſhort petioles or ſubſeſſile, ternate. Leaflets wedge-ſhaped, ſubſeſſile, blunt, quite entire or very ſlightly emarginate, villoſe at the edges, ſmooth on the upper ſurface, hirſute at the back, having very many ſcattered yelloviſh calluſes viſible with a glaſs, about half an inch in length. Peduncles not jointed at the baſe, axillary, ſolitary, alternate, filiform, ſomewhat villoſe, pale purple, two inches long, ſpreading, flaccid; with alternate bractes above the middle. Calycine leaflets lanceolate, acuminate, ſomewhat villoſe, erect, pale purple. Corolla ſeveral times larger than the calyx: claws erect, yellow: borders wedge-ſhaped, rounded, longer than the claws, ſpreading very much, ſmooth, pale purple. Filaments connate: interior toothleſs, equal, ſomewhat hirſute with little capitate hairs: exterior ſmooth. Anthers incumbent, yellow. Germ very ſhort, pale greeniſh yellow, hirſute at top, callous. Styles very hirſute with ſimple hairs.

Native of the Cape of Good Hope. It flowers in Europe in ſeptember and october.—This ſpecies is remarkably rough in its wild ſtate, but puts off much of its roughneſs when cultivated[5].

27. Bulb roundiſh, with a brown ſkin, the ſize of a hazel nut. Stem round, hirſute, commonly undivided, almoſt upright, weak, ſlender, greeniſh, about eight inches long, ſcaly at the baſe. Leaves alternate, on very ſhort petioles, ternate. Leaflets narrow lanceolate, ſharpiſh, quite entire, ſcarcely dotted, green on both ſides, ſmooth above, ſomewhat hirſute underneath and having numerous minute yelloviſh-brown calluſes diſcoverable with the microſcope, villoſe at the edges, ſubſeſſile, reflex and ſpreading very much, half an inch long or a little more. Peduncles not jointed at the baſe, axillary, ſolitary, alternate, roundiſh, villoſe, pale, flaccid, four inches long, having alternate bractes at top. Calycine leaflets lanceolate, bluntiſh, hirſute, ciliate, almoſt upright, pale green, ſometimes without any ſpots, ſometimes having orange-coloured ſpots both above and below, and a ſingle browniſh ſpot on each ſide at the edges. Corolla four or five times as long as the calyx: claws erect, yelloviſh, the length of the calyx: borders obovate, rounded, wide, ſpreading very much, very pale violet within, on the outſide pale with one ſide dirty yellow and ſomewhat villoſe. Filaments connate: interior gibbous-toothletted, thinly hirſute with capitate hairs; exterior alſo hirſute. Anthers incumbent, yellow. Styles hirſute with ſimple hairs.

Native of the Cape of Good Hope. In Europe it flowers in october and november[6].

28. Bulb roundiſh, larger than a hazel nut, with a browniſh ſkin, compoſed of fleſhy, very thick, ovate-acuminate, looſe ſcales, forming as it were ſo many bulbs; hence lobed. Stem round, almoſt upright, weak, ſomewhat villoſe, browniſh purple, from the thickneſs of a pigeon's quill to only half the ſize, from ſix inches to a foot in height, branched. Leaves alternate, ternate, ſpreading very much, numerous, ſubſeſſile. Leaflets alſo ſubſeſſile, blunt, quite entire, appearing to be emarginate on account of the middle tip being reflexed, hirſute underneath and at the edges, ſmooth above, half an inch long to a quarter. Peduncles axillary, ſolitary, jointed at the baſe, round,

[1] Jacquin. [2] Idem. [3] Idem. [4] Idem. [5] Idem. [6] Idem.

villose, flaccid, from two to three inches long, slender, pale, with alternate bractes at top. Calycine leaflets lanceolate, acute, hirsute, ciliate, erect, green with white edges. Corolla five times as long as the calyx: claws erect, yellow, twice as long as the calyx: borders obovate, blunt, wide, spreading very much, violet verging either to purple or blue, with the back on one side yellow and villose. Filaments united at the base: interior toothless, unequal; exterior equal. Anthers oblong, incumbent, yellow. Germ pale green, very hirsute at top, callous. All these parts hirsute with simple hairs.

Native of the Cape of Good Hope. In Europe it flowers in october and november.—A very large specimen is figured in Jacquin's rare plants, as a variety of *O. hirta*, in his *Monographia* it is represented smaller and more branched [1].

29. Bulb ovate, acute, the size of a hazel nut, with a ferruginous skin, loose. Stem round, slender, somewhat hirsute, fleshy, weak: so that it is seldom really upright, scaly at the base, brownish purple, about half a foot high. Leaves alternate, ternate, the lower on short petioles, the rest subsessile. Leaflets subsessile, subcuneiform, rounded, quite entire, a little converging, smooth above, underneath and at the edges somewhat rough-haired, half an inch long. Peduncles axillary, solitary, very shortly jointed at the base, round, somewhat villose, flaccid, pale, about two inches long, with alternate bractes at top. Calycine leaflets lanceolate, acute, ciliate, hirsute, erect, green with the edges purple at bottom. Corolla several times longer than the calyx: claws erect, twice as long as the calyx, yellow: borders obovate, rounded, spreading very much, purple above, underneath pale purple with one side yellow and somewhat villose. Filaments connate at the base: interior toothless, unequal, hirsute with capitate hairs; exterior smooth. Anthers oblong, incumbent, yellow. Germ pale green, hirsute at top, callous. Styles hirsute with simple hairs.

Native of the Cape of Good Hope. In Europe it flowers from october to december [2].

Jacquin at first took this for *O. hirta*, and it is figured under that name in his rare plants, with larger leaves and flowers. Another specimen is figured in his *monographia*.

30. Bulb roundish or ovate, with a brown skin, less than a hazel nut. Stem round, slender, very hirsute, leafless to the middle, with minute wandering scales, sometimes but very seldom having an axillary flowering branchlet at top, weak, prostrate, rising up towards the top, from six inches to near a foot in height. Leaves on very short petioles, alternate, ternate, the upper ones collected into a close hoary rose. Leaflets subsessile, lanceolate, acute, quite entire, from reflex spreading very much, green, ciliate at the edges with villose hairs, smooth above, underneath dotted, rough-haired, having many obscure calluses visible by a glass, half an inch long, but in some individuals scarcely three lines in length. Peduncles not jointed at the base, axillary, solitary, very villose, flaccid, an inch and half long, with alternate, approximating bractes at top. Calycine leaflets lanceolate, acute, ciliate, villose, pale green, erect. Corolla several times longer than the calyx. Claws upright, almost twice as long as the calyx, yellow: borders wide, obovate, rounded with a small point stretched out, spreading very much, deep red within, on the outside paler red, with one side at the back yellow and somewhat villose. Filaments united at the base: interior unequal, hirsute with simple hairs; the toothlets smooth: exterior hirsute also with simple hairs. Anthers incumbent, yellow. Styles hirsute with simple hairs.

Native of the Cape of Good Hope. In Europe it flowers from september to november. This species is easily distinguished from all the rest by having its leaves at the ends of the stem and branches very closely collected into a form like a double rose, spreading and very hoary [3].

31. Bulb elongated ovate, half an inch long or more, covered with a brown skin, putting forth a long thick fibre from the base. Stem round, the thickness of a pigeon's quill, smooth, pale green or dirty purple, half a foot long or more, almost upright at the base, then reclining and ascending, branched at the base, having distant scales at bottom, in other parts leafy, at all the scales and leaves jointed. Leaves alternate, distich, smooth, ternate. Petiole jointed at the base, round, very slender, spreading, from one to two inches in length, each joint winged with a large embracing white pellucid very converging stipule, a little connate above, perforated, obcordate if it burst so as to be expanded. Leaflets obcordate, appearing dotted on both sides when examined by a glass, green, on very short petioles, scarcely half an inch in length, all equal. Peduncles jointed at the base, axillary, solitary, alternate, round, smooth, spreading, about the same length with the leaves, with opposite bractes directly under the calyx. Calycine leaflets smooth, oblong, blunt, pale green with white edges, spreading. Corolla smooth, three times as long as the calyx, dirty yellow within, pale yellow on the outside: petals obovate, rounded, wide, spreading very much at top. Filaments connate at the base, smooth: interior toothletted, equal, converging at top. Anthers oblong, incumbent at their origin, upright, yellow. Germ ovate, five-grooved, smooth at bottom, hirsute with club-shaped hairs at top. Styles smooth. Seeds solitary.

Native of the Cape of Good Hope. In Europe it flowers in december and january [4].

32. Bulb ovate, acute, the size of a pea, often several inclosed in one brown skin. Stem filiform, weak, an inch or a little more in length, round, appearing villose when magnified. Leaves alternate, ternate, almost upright, at bottom few, at top several approximating. Petiole jointed at the base, round, slender, somewhat villose, one or two inches in length. Leaflets subsessile, villose at the edges, smoothish on both sides with minute dots appearing pellucid in the light, three or four inches long. Peduncles axillary, solitary, jointed at the base, round, somewhat villose, upright, longer than the leaves, with bractes alternate at top. Calycine leaflets lanceolate, acute, ciliate, hirsute, erect, green with white edges, and oblong orange-coloured calluses below the tip. Corolla five times as long as the calyx, smooth: claws short, upright, yellow: borders obovate, rounded, spreading very much, very pale violet on both sides. Filaments united at the base: interior unequal, somewhat hirsute with a few capitate hairs: exterior equal, hirsute in like manner. Anthers oblong, incumbent, yellow. Germ oblong, pale yellowish green, with hairs and orange calluses at top. Styles very short, densely hirsute with capitate hairs.

Native of the Cape of Good Hope. In Europe flowering in november and december. This and the following species connect the caulescent with the stemless *Oxalides* [5].

33. Bulb roundish, about the size of a hazel nut, with a black hard skin, and commonly a double nucleus, putting forth a slender white jointed root, with a scale at each joint, having fibres on every side, here and there bulbiferous, creeping horizontally, from one to six inches in length. Stem round, the thickness of a pigeon's quill, somewhat villose, upright, below the leaves scaly and about an inch long, and then two or three inches more in length. Leaves alternate, ternate. Petiole jointed at the base, round, villose, weak, red or green, from three to six inches long. Leaflets sessile, slightly emarginate, appearing dotted with a magnifier on both sides, somewhat villose at the edges and along the dorsal nerve, in other parts smooth, green, but when old variegated with red and yellow. Scapes axillary, jointed at the base, round, somewhat villose, red, flaccid, the length of the leaves, with alternate green bractes below the middle. Calycine leaflets oblong, sharpish, ciliate, hirsute, erect, green. Corolla six times as long as the calyx: claws upright, twice as long as the calyx, yellowish: borders obovate, rounded, wide, spreading very much, pale

[1] Jacquin monogr. [2] Idem. [3] Idem. [4] Jacquin. [5] Idem.

with

with a bluſh of purple, ſomewhat villoſe at the back on one ſide. Filaments united at the baſe: interior equal, with capitate hairs thinly ſcattered over them, and the toothlets alſo hirſute; as are likewiſe the exterior ones. Anthers oblong, incumbent, yellow. Germ oblong, pale green, villoſe at top. Styles very ſhort, very hirſute with ſimple hairs.

Native of the Cape of Good Hope. In Europe it flowers in november and december.

This ſpecies increaſes abundantly by its creeping roots generating many bulbs in their courſe, ſo that the pots are in a ſhort time full of plants, all thus cauleſcent. Theſe numerous plants have flowered only once in four years that they have been cultivated [a].

34. Bulb roundiſh, twice as large as a pea, half looſe, with a ſoft compreſſile ſkin, lanuginoſe as it were, and of a browniſh ſtraw-colour. Stipe ſubterraneous, from a line to an inch in length, having a few ſcales at top, terminating in an umbel of a few leaves and flowers. Leaves few, upright or decumbent, ovate, obovate or oblong, emarginate or quite entire, green on both ſides, and appearing dotted in the microſcope, hirſute at the edges and on the midrib with capitate hairs, in other parts ſmooth, about an inch long; on a petiole of the ſame length, hirſute with capitate hairs, ſhortly jointed below the leaf, as it is at the baſe. Scapes from one to four, not jointed at the baſe, weak, hirſute with capitate hairs, longer than the leaves, yelloviſh green, without bractes. Calycine leaflets oblong, bluntiſh, erect, hirſute with capitate hairs and ciliate, pale green at bottom, variegated at top with blood-red ſpots and orange dots, whitiſh at the edges. Corolla ſix times as long as the calyx, bell-ſhaped: claws upright, villoſe, yellow: borders obovate, rounded, pale purple, with the back on one ſide villoſe. Filaments connate: interior gibbouſly toothletted, unequal, hirſute with capitate hairs: exterior equal, the ſhorteſt of all the ſpecies, ſmooth. Anthers oblong, incumbent, yellow. Germ roundiſh, pale green, capitately hirſute at top. Styles pale, hirſute with capitate hairs.

This and the two next ſpecies are ſo alike in habit, leaves, bulb and flowers, that they can ſcarcely be diſtinguiſhed. But the genitals are very different. Beſides the length of the ſtyles, in this the interior filaments are gibbouſly toothletted and unequal, the exterior extremely ſhort. In *O. monophylla* the filaments are toothleſs and equal. They are ſo alſo in *O. reflexa*, but in this they are ſingularly beaked at the tip, in which it differs from all the other ſpecies [b].

35. Bulb roundiſh. Stipe ſhort. Leaves ſpreading, from oblong obovate, almoſt entire, half an inch long, jointed below the leaf, but not at the baſe. Scapes few, rather longly jointed at the baſe. Filaments very ſhortly connate at the baſe, ſmooth. In other reſpects it agrees with the preceding, except in the differences pointed out above [c].

36. Stipe from a line to an inch in length. Leaves erect or decumbent, as in n. 34. jointed below the leaf, not at the baſe. Scapes from one to four, rather longly jointed at the baſe, weak. Calycine leaflets as in n. 34. Corolla alſo as in that. Interior filaments at the top blunt and club-ſhaped, on the ſide at top putting forth a beak, which is ſmooth, the other parts hirſute with capitate hairs: exterior, awl-ſhaped, almoſt ſmooth. Anthers faſtened to the beaks of the interior and tips of the exterior filaments. Styles very ſmooth. In other reſpects it agrees with the two preceding, except in the differences pointed out above [d].

37. Bulb roundiſh, with a brown ſkin, the ſize of a hazel nut, often looſe. Stipe partly ſubterraneous, about an inch long, and then ſtanding out, ſhorter, ſcaly, leafleſs, browniſh, the thickneſs of a pigeon's quill, upright, terminated by a thin umbel of leaves and flowers. Leaves few, generally three, upright, wholly ſmooth. Petiole jointed at the baſe, thick, half round, more or leſs purple, an inch and half long, widely winged. Leaflets ſeſſile, erect, very blunt, emarginated, dotted on both ſides, on the edges and along the wings cartilaginous-crenulate, curled and rigid, underneath ſometimes blood-red, from two to three inches long. Scapes few, jointed at the baſe, compreſſed a little, ſhining, thick, pale green, almoſt upright, half a foot high, with alternate, approximating bractes a little below the flower. Calycine leaflets ovate, ſharpiſh, ſmooth, green, upright with the tips ſpreading. Corolla five times as large as the calyx: claws erect, yellow: borders wide, rounded, ſpreading very much, the length of the claws, white with the back on one ſide obſcurely yelloviſh red. Filaments connate at the baſe: interior toothletted, equal, hirſute with capitate hairs; the toothlets ſmooth: exterior wholly ſmooth. Anthers incumbent, yellow. Germ ovate, ſmooth, pale green. Styles very long, hirſute with capitate hairs. This has ſometimes one or two ſimple leaves, but they are never ternate. In ſome individuals the leaflets are much ſmaller, and ſcarcely an inch in length [e].

38. Bulb ovate, with a brown ſkin, the ſize of a hazel nut. Stipe partly ſubterraneous, about an inch long, ſcaly, then ſtanding out, ſhorter, ſcaly, leafleſs, almoſt upright, terminated by an umbel of leaves and flowers. Leaves ſeveral, erect, ſmooth, very ſeldom ſimple, never ternate. Petiole jointed at the baſe, half round, about two inches long, winged. Leaflets bluntiſh, quite entire, or very ſeldom ſlightly emarginate, from two to three inches long, green on both ſides, appearing dotted in the microſcope, along the edges together with the wings cartilaginous-crenulate, erect. Scapes few, jointed at the baſe, roundiſh, longer than the leaves, pale green, ſmooth, almoſt upright but weak, with alternate bractes above the middle. Calycine leaflets lanceolate, ſharpiſh, ſmooth, erect, green. Corolla four times as long as the calyx: claws erect, yellow; borders wide, obovate, rounded, ſpreading very much, yellow on both ſides. Filaments united at the baſe: interior toothletted, equal, hirſute with capitate hairs, with ſmooth toothlets: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale greeniſh yellow, very ſmooth. Styles hirſute with capitate hairs [f]. It has the trivial name from its long binate leaflets, reſembling aſſes ears.

39. Bulb roundiſh, pale *fleſh*-colour, with a brown ſkin, the ſize of a hazel nut. Stipe, the part underground about an inch, above ſhorter, ſcaly, leafleſs, browniſh, almoſt upright, terminated by a thin umbel of leaves and flowers. Leaves few, commonly two only, upright, ſmooth, very ſeldom ſimple, never ternate. Petiole jointed at the baſe, half round, about two inches long, always winged, but the wings ſometimes ſo narrow as to be ſcarcely conſpicuous. Leaflets blunt, quite entire or ſlightly emarginate, from one to two inches in length, appearing in the microſcope dotted on both ſides, green, cartilaginous-crenate on the edges and wings, erect. Scapes few, jointed at the baſe, longer than the leaves, roundiſh, pale green, almoſt upright, ſmooth, with approximately alternate bractes a little below the flower. Calycine leaflets ovate, ſharpiſh, ſmooth, erect with the tips ſlightly ſpreading, green. Corolla four times as long as the calyx: claws erect, yellow: borders wide, rounded, ſpreading very much, the length of the claws, white with the back on one ſide reddiſh. Filaments connate at the baſe: interior equal, hirſute with capitate hairs; toothlets ſmooth: exterior ſmooth. Anthers incumbent, whitiſh. Germ ovate, pale green, very ſmooth. Styles hirſute with capitate hairs [g]. It has the trivial name from the binate leaves reſembling a hare's ear.

40. Bulb ovate, ſmaller than a hazel nut; covered with a brown ſkin. Stipe ſubterraneous, one or two inches long, almoſt the thickneſs of a pigeon's quill, having a few ſcales at top, and being bulb-bearing at bottom, terminating in an umbel of leaves and a few flowers. Leaves ſeveral, the lower ones binate, the reſt ternate, almoſt upright. Petiole jointed at the baſe and purpliſh, half round, ſmooth, more or leſs wingred, about two inches long, with the wings cartilaginous-ſcabrous at the edges. Leaflets lanceolate,

[a] Jacquin. [b] Idem. [c] Idem. [d] Idem. [e] Idem. [f] Idem. [g] Idem.

ſharpiſh,

ſharpiſh, ſeſſile, cartilaginous-ſcabrous at the edges, ſmooth on both ſides, glaucous green, blood-red underneath on the midrib, an inch and half or two inches long. Scapes few, not jointed at the baſe, round, ſmooth, weak, almoſt as long as the leaves, pale green, with a ſingle bracte at bottom not jointed. Calycine leaflets lanceolate, acute, ſmooth, upright, pale green with a tinge of red. Corolla four times as long as the calyx, bell-ſhaped, yellow: claws erect, a little longer than the calyx: borders obovate, rounded, quite entire, ſpreading very much. Filaments very ſlightly united at the baſe, ſmooth, membranaceous-compreſſed: interior toothleſs, equal. Anthers oval, incumbent, pale. Germ ovate, ſmooth, pale green, red at top. Styles ſomewhat villoſe with very ſhort thin-ſpread hairs [a].

41. Bulb roundiſh, with a brown ſkin, the ſize of a hazel nut, often looſe. Stipe about an inch, partly under ground, partly above, ſcaly, leafleſs, nearly as thick as a reed at top, almoſt upright, terminated by a thin umbel of leaves and flowers. Leaves few, upright, wholly ſmooth. Petiole jointed at the baſe, thick, half round, purpliſh, an inch and half long. Leaflets ſeſſile, erect, obovate or almoſt oblong, blunt, often emarginate, flat not waved, cartilaginous-toothed at the edges, appearing dotted on both ſides in the microſcope, green, two inches and a half long, and almoſt an inch and half wide. Scapes few, jointed at the baſe, compreſſed, thickiſh, longer than the leaves, almoſt erect, with approximately alternate bractes. Calycine leaflets ovate, bluntiſh, green with purpliſh edges, ſmooth, erect with the tips ſpreading a little. Corolla ſeveral times longer than the calyx: claws erect, pale yellow: borders wide, rounded, ſpreading very much, yellow within, pale yellow on the outſide. Filaments connate at the baſe: interior toothletted, equal, very hirſute with capitate hairs, but the toothlets ſmooth: exterior hirſute in the ſame manner. Anthers incumbent, yellow. Germ ovate, ſmooth, pale green. Styles of a middling length, very hirſute with capitate hairs [b].

42. Bulb ovate, with a blackiſh-brown ſkin the ſize of a hazel nut. Stipe ſubterraneous, round, white, almoſt as thick as a pigeon's quill, about an inch in length, terminated by a thin umbel of leaves and flowers. Leaves few, ſpreading. Petiole jointed at the baſe, half round, thick, hirſute, blood-red, about two inches long. Leaflets blunt, villoſe at the edges, green and ſomewhat villoſe on the upper ſurface, dotted at the back, ſmooth except the nerve, which is hirſute, paler green or elſe more or leſs blood-red, about an inch and half in length, ſeſſile, quite entire. Scapes few, jointed at the baſe, compreſſed, erect, whitiſh, ſomewhat villoſe, the length of the petioles or ſometimes much longer, with bractes approximately alternate below the middle. Calycine leaflets lanceolate, acute, ſomewhat hirſute, ciliate with capitate and ſimple hairs mixed, pale green with blood-red edges, and the tip ſoot-coloured, erect. Corolla ſeveral times longer than the calyx, yellow on both ſides, but paler without: claws erect, ſomewhat villoſe: borders wedge-ſhaped, rounded, the length of the claws, ſpreading very much, a little villoſe on one ſide of the back. Filaments connate at the baſe: interior toothletted, equal, hirſute with capitate hairs, but the toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, hirſute at top, pale green, callous. Styles very hirſute with the upper hairs capitate and the reſt ſimple [c].

43. Bulb ovate, minute, with a blackiſh brown ſkin, looſe. Stipe ſubterraneous, an inch long, of a dirty whitiſh colour, nearly as thick as a pigeon's quill, terminated by a thin umbel of leaves and flowers. Leaflets few, ſometimes no more than two, almoſt upright or ſpreading a little. Petiole jointed at the baſe, compreſſed a little, from two to three inches in length, ſomewhat hirſute, blood-red. Leaflets ſeſſile, bluntiſh, villoſe at the edges, dotted on both ſides, green and ſomewhat hirſute above, underneath ſmooth with the nerve only a little rough-haired, ſhining and of a dark blood-red colour, the lateral ones an inch long. Scapes few, jointed at the baſe, roundiſh, villoſe, white, almoſt upright, the length of the leaves, with bractes approximately alternate below the middle. Calycine leaflets lanceolate-ovate, ſharpiſh, ciliate, hirſute, upright, purple. Corolla ſeveral times larger than the calyx, yellow, paler on the outſide: claws upright, three times as long as the calyx, villoſe: borders rounded, broad-wedge-ſhaped, ſpreading very much, the length of the claws, villoſe at the back on one ſide. Filaments united at the baſe: interior toothletted, equal, hirſute with very ſhort ſimple hairs; toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale green, hirſute at top, callous. Styles hirſute with ſimple hairs [d].

44. Stipe ſubterraneous, terminating in a poor umbel of leaves and flowers. Leaves few, minute, wholly ſmooth. Petiole filiform, the third part of an inch in length. Leaflets quite entire. Scape ſingle, half an inch long, ſmooth, upright, with very ſmall ſmooth bractes, approximately alternate below the flower. Calycine leaflets lanceolate, ſharpiſh, ſmooth, upright. Corolla five times as long as the calyx, bell-ſhaped, ſmooth: claws upright, yellowiſh: borders obovate, rounded, white. Filaments united at the baſe, ſmooth: interior equal. Anthers oblong, incumbent. Germ oblong, ſmooth, ſhort. Styles hirſute with ſimple hairs [e].

45. Bulb ovate, the ſize of a hazel nut, with a black ſkin. Stipe out of the ground, having a few ſcales and one or two leaves, round, villoſe, often ſmooth at bottom, ſlender, weak, almoſt upright, terminated by a denſe umbel of leaves and flowers. Leaves ſeveral, upright and ſpreading very much. Petiole widening at the baſe, ciliate, orange-ſpotted at the edges underneath, not jointed, ſlender, hirſute, from two lines to two inches and a half in length. All the leaflets exactly oblong, on very ſhort petioles, quite entire or ſlightly emarginate, green and in the microſcope appearing dotted on both ſides, ſomewhat villoſe at the edges and underneath, ſmooth above, about half an inch in length. Scapes ſeveral, not jointed at the baſe, ſlender, upright, ſomewhat hirſute, longer than the leaves; bractes ſubalternate, directly under the calyx. Calycine leaflets long lanceolate, ſharp, villoſe, ciliate, green, upright. Corolla four times as long as the calyx: claws upright, yellow, tubular: borders wedge-ſhaped, rounded, ſpreading very much, almoſt the length of the claws, red with one ſide of the back paler and ſomewhat villoſe. Filaments connate at the baſe: interior equal. Anthers incumbent, yellow. Germ oval, pale green, hirſute all over, callous. All theſe parts are hirſute with very minute capitate hairs [f].

46. Bulb ovate, ſlender, with a blackiſh-brown ſkin, almoſt an inch in length. Stipe out of ground, round, almoſt half the thickneſs of a pigeon's quill, having a few ſcales but no leaves, hirſute, browniſh-green, three or four inches long, procumbent, terminated by an umbel of leaves and flowers. Leaves very many, ſpreading. Petiole jointed at the baſe, ſlender, dirty purple, round, hirſute, about an inch long. Leaflets ſubſeſſile, flat, villoſely ciliate at the edges, ſmooth above, villoſe underneath, appearing in the microſcope dotted on both ſides, recurved, an inch long. Scapes ſeveral, jointed at the baſe, round, villoſe, upright, purpliſh, about the ſame length with the petioles, with bractes extremely minute, and directly under the calyx. Calycine leaflets lanceolate-acute, hirſute, ciliate, upright, pale green. Corolla four times as long as the calyx: claws forming a long tube, upright, ſomewhat villoſe, dirty yellow: borders lanceolate, bluntiſh, ſomewhat villoſe on the outſide, ſhorter than the claws, ſpreading very much, red. Filaments united at the baſe: interior toothleſs, unequal, a little hirſute with a few ſlightly capitated hairs: exterior unequal, hirſute in like manner. Anthers twin, oval, upright, yellow. Germ pale green, thinly hirſute at top. Styles wholly ſmooth [g].

[a] Jacquin. [b] Idem. [c] Idem. [d] Idem. [e] Jacquin from Thunberg. [f] Idem. [g] Jacquin.

47. Bulb ovate, with a blackiſh-brown ſkin, ſmaller than a hazel nut. Stipe out of the ground, round, ſlender, having a few ſcales but ſeldom any leaves, ſometimes a ſingle leaflet at top, hirſute, brown, from four to ſeven inches long, at firſt upright, but by age becoming wholly procumbent, terminated by a cloſiſh umbel of leaves and flowers, and ſometimes, but rarely, lengthened out into another umbel. Leaves ſeveral, almoſt upright. Petiole widened at the baſe, not jointed, ſlender, purpliſh, hirſute, about an inch long. Leaflets ſubſeſſile, quite entire or ſlightly emarginate, villoſe at the edges, appearing in the microſcope dotted on both ſides, green, ſmooth above, ſomewhat villoſe underneath, three quarters of an inch long. Scapes ſeveral, not jointed at the baſe, round, villoſe, upright, purpliſh, about the ſame length with the petioles; bractes approximately alternate a little way below the calyx. Calycine leaflets lanceolate, acute, erect, ciliate, villoſe, purpliſh. Corolla ſeveral times longer than the calyx: claws ſomewhat villoſe, dirty yellow, upright, forming long tubes: borders lanceolate, bluntiſh, ſhorter than the claws, ſomewhat villoſe on the outſide, ſpreading very much, purpliſh. Filaments connate at the baſe: interior unequal, ſmooth: exterior ſmooth. Anthers upright, yellow. Germ oblong, yelloviſh green, ſomewhat hirſute at top. Styles ſtanding out as far as the middle of the borders of the corolla, hirſute at the baſe and towards the tip with a very few ſimple hairs[g].

48. Bulb roundiſh, the ſize of a hazel nut, covered with a brown ſkin, ſometimes looſe. Stipe ſtanding out, filiform, browniſh, ſmooth, about half a foot long, very weak and wholly proſtrate, at bottom leafleſs with a few ſcales, above having ſolitary leaves and frequently an umbel, terminating in a thin umbel of leaves and flowers. Petiole jointed at the baſe, filiform, ſmoothiſh, from an inch to an inch and half in length, looſe. Leaflets ſubpetioled, blunt, ſlightly emarginate, ſmooth above, obſcurely villoſe underneath and at the edges, green, without any conſpicuous callus, from half an inch to an inch in length. Scapes few from all the umbels, and ſometimes alſo one from the axil of the upper leaf, jointed at the baſe, longer than the leaves, thicker than the petioles, appearing villoſe when magnified, looſe; bractes approximately alternate at top. Calycine leaflets lanceolate, acute, ſomewhat ciliate and villoſe, green with the tips and edges of the baſe ferruginous, upright. Corolla ſeveral times longer than the calyx: claws upright, yelloviſh: borders wide, rounded with a little point, ſpreading very much, pale red within, whitiſh red on the outſide. Filaments connate at the baſe: interior equal, ſomewhat hirſute with capitate and ſimple hairs mixed: exterior very thinly hirſute in the ſame manner. Anthers incumbent, yellow. Germ pyramidal, yelloviſh green, hirſute at top. Styles very cloſely hirſute like the filaments[h].

49. Bulb roundiſh, often an inch in diameter, covered with a brown ſkin, looſe. Stipe ſtanding out, a foot or eighteen inches long, round, ſmaller than a pigeon's quill, minutely and denſely villoſe, brown, below the middle having a few ſcales but no leaves, above the middle leafy and ſometimes having a branchlet; when young wholly upright, but afterwards more or leſs reclining, and even entirely procumbent on account of its weakneſs and the weight of the umbel; terminated by a denſer looſe umbel of leaves and flowers. Leaves ſeveral. Petiole jointed at the baſe, filiform, from one to two inches long, villoſe, browniſh purple, looſe. Leaflets on very ſhort petioles, emarginate, ſmooth above, very ſhortly pubeſcent underneath and at the edges when examined by a glaſs, and having yellow calluſes ſcattered over the whole back, about half an inch in length. Scapes ſeveral, jointed at the baſe, ſomewhat villoſe, looſe, thicker and longer than the petioles; bractes approximately alternate at top. Calycine leaflets linear-lanceolate, blunt, thinly ciliate and villoſe, green with brown tips, upright. Corolla four times as long as the calyx: claws upright, yelloviſh: borders wide, rounded, very blunt, ſmooth, ſpreading very much, pale red within, and ſtill paler on the outſide. Filaments united at the baſe: interior unequal, hirſute with ſimple hairs: exterior ſomewhat hirſute in the ſame manner. Anthers incumbent, yellow. Germ oblong, yelloviſh green, extremely villoſe above the middle. Styles hirſute with ſimple hairs[i].

50. Bulb roundiſh, the ſize of a hazel nut, covered with a brown ſkin, ſometimes looſe. Stipe above ground, filiform, browniſh, ſmooth, from one to four inches long, very weak, and always wholly proſtrate from its extreme ſlenderneſs, moſtly leafleſs and having only a few minute ſcales, except at top, where there is a leaf or one or two umbels; it is terminated alſo by a denſer looſe umbel of leaves and flowers. Leaves ſeveral. Petiole jointed at the baſe, filiform, ſmoothiſh, from one to two inches long, looſe. Leaflets ſubſeſſile, blunt, often emarginate, ſmooth above, underneath and at the edges ſcarcely villoſe when magnified, green, without any conſpicuous callus, from half an inch to an inch in length. Scapes ſeveral, jointed at the baſe, longer than the leaves, thicker than the petioles, appearing villoſe when magnified, looſe; bractes approximately alternate at top. Calycine leaflets lanceolate, acute, ſomewhat villoſe and ciliate, green with the tips ferruginous, upright. Corolla four times as long as the calyx and longer: claws upright, ſomewhat yelloviſh: borders wide, rounded with a little point, deep red within, very pale red on the outſide, ſpreading very much. Filaments connate at the baſe: interior unequal. Anthers incumbent, yellow. Germ ovate, ſmooth, pale green[k].

51. Bulb ovate, half an inch long, covered with a black ſkin, within which are frequently ſeveral bulbs, hence when cultivated it has almoſt always many ſtipes: theſe are out of the ground, have a few ſcales on them, are round, ſlender, have a very few hairs ſcattered over them, are ſix inches long, ſometimes leafleſs, ſometimes having a ſingle leaf at top, when young almoſt upright, but afterwards wholly procumbent, terminated by a denſe umbel of leaves and flowers. Leaves ſeveral, upright and ſpreading a little. Petiole jointed at the baſe, filiform, villoſe, from one to two inches in length. Leaflets ſubſeſſile, wedge-form-linear, emarginate, at the edges and underneath appearing ſomewhat villoſe when magnified, above ſmooth and dotted, underneath having two orange-coloured calluſes below the tip, about half an inch in length. Scapes ſeveral, jointed at the baſe, round, a little hirſute at top with capitate hairs, in other parts with ſimple ones, almoſt upright, longer than the petioles and twice as thick; bractes alternate, approximating, and ciliated at top with capitate hairs. Calycine leaflets lanceolate, acute, erect, ciliate and hirſute with capitate or ſimple hairs, green with the edges blood-red and two oblong orange-coloured calluſes below the tip connected at top. Corolla four times as long as the calyx: claws erect, yellow: borders obovate, rounded, quite entire, wide, ſpreading very much, white with one ſide of the back blood-red. Filaments connate at the baſe: interior unequal, hirſute with ſimple and capitate hairs: the toothlets ſmooth: exterior very ſparingly hirſute in the ſame manner. Anthers incumbent, ſulphur-coloured. Germen yelloviſh green, ſomewhat hirſute at top. Styles hirſute with ſimple and capitate hairs[l].

Dr. Smith, whoſe deſcription does not in general differ materially from the above, remarks, that the flowers are expanded in the ſunſhine only, have no ſcent, but are beautiful and extremely elegant even when cloſed; that the petals are ſeparate at the baſe, but a little above it united into a tube, then again ſeparated, folded over each other to the left, white with an exquiſite red border, that the five longeſt filaments are but half the length of the corolla, with didymous anthers; and five other very ſhort filaments, without anthers, are attached to the longer ones, and ſtand between the ſhorter; that the germ is ſmooth and pellucid, full of little protuberances occaſioned by

[g] Jacquin. [h] Idem. [i] Idem. [k] Idem. [l] Idem.

the prominent rudiments of the ſeeds, the ſtyles the length of the longer ſtamens.

Introduced in 1774, by Mr. Francis Maſſon [n]. It flowers abundantly in the hot-houſes of the botanic garden at Chelſea in the winter [n].

52. Bulb ovate, covered with a footy ſkin, ſmaller than a hazel nut. Stipe appearing ſomewhat hirſute when examined by a glaſs, having a few ſcales, and often one or two leaves, extremely weak ſo as to be wholly procumbent. Petiole round, ſlender, appearing villoſe when magnified, about an inch long. Leaflets underneath ſomewhat hirſute, and having generally two ferruginous ſpots below the tip, for they are ſometimes wanting, half an inch long or a little more. Scapes ſomewhat villoſe, nearly twice as long as the leaves, almoſt upright, but weak. Calycine leaflets hirſute with capitate hairs, green with two linear orange-coloured calluſes on the back at the tip. Corolla bell-ſhaped: borders white with one margin of the back yellow tinged with purple. Interior filaments hirſute with capitate hairs: exterior ſmooth. Styles hirſute with ſimple hairs.

53. Bulb ovate, with a black ſkin, half the ſize of a hazel nut. Stipe almoſt upright, ſmooth or ſomewhat villoſe, purple at bottom, from two to four inches long, ſcaly at the baſe, ſometimes leafleſs, ſometimes leafy all over; and even having barren branchlets; the umbel of leaves and flowers that terminates it being elongated, but barren. Petiole an inch in length, or much ſhorter. Leaflets blunt or retuſe, very thinly hairy on both ſides, converging, underneath below the tip and at the edges having from three to nine orange-coloured calluſes, ſcarcely half an inch in length. Scapes ſhortly jointed at the baſe, purpliſh, two inches long and more: bractes minute, ſomewhat villoſe, orange-coloured at top, above the middle. Calycine leaflets oblong, ſharpiſh, villoſe, purple mixed with green, ciliate, with two oblong, orange-coloured calluſes at the tip underneath. Borders of the corolla rounded-wedge-ſhaped, pale with a tinge of fleſh-colour, outwardly on one ſide red-purple and ſomewhat villoſe. Interior filaments hirſute with capitate hairs: exterior ſmooth. Anthers pale yellow or whitiſh. Styles hirſute with ſimple hairs.

54. Bulb roundiſh, the ſize of a hazel nut or even of a walnut, covered with a brown ſkin, having ovate acuminate looſe ſcales, fleſh-coloured or pale and fleſhy. Stipe from half an inch to ſix inches in height, upright but weak, appearing ſomewhat villoſe in the microſcope, purpliſh or browniſh, the thickneſs of a pigeon's quill, ſometimes leafleſs and having only diſtant ſcales, ſometimes leafy, commonly quite ſimple but ſometimes having a ſingle branchlet or two, terminated by a cloſely leafy and many-flowered umbel. Leaves very many. Petiole very ſlightly jointed at the baſe, purple and green, from half an inch to three or four inches in length. Leaflets emarginate, appearing in the microſcope dotted on both ſides, ſmooth above, having a very few hairs underneath and two orbicular orange-coloured calluſes below the tip, channelled and converging, from half an inch to two inches in length. Scapes much thicker than the petioles, greeniſh brown or purple: bractes at top alternate or nearly oppoſite, blunt, having two oblong tawny calluſes underneath below the tip. Calycine leaflets lanceolate-oblong, blunt, ſomewhat hirſute, green with the edges purple below, having two calluſes like the bractes, upright in the flower, afterwards half bent back. Corolla three times as long as the calyx: borders obovate, rounded, ſpreading very much, within pale purple roſe-colour, on the outſide dirty whitiſh with one ſide yelloviſh and ſomewhat villoſe. Anthers ſulphur-coloured. Style hirſute at bottom with ſimple, at top with capitate hairs. Stigma very pale yellow. This is deſcribed by Jacquin in his collections, and figured in his *Icones variores*, under the name of *O. verſicolor*. The three laſt indeed are probably conſidered by Linnæus and Thunberg as varieties of *O. verſicolor* [o].

55. Bulb ovate, almoſt the ſize of a hazel nut, with a blackiſh-brown ſkin, often looſe at top. Stipe ſtanding out, round, ſcaly, brown, villoſe, procumbent, leafleſs, ſlender, two or three inches long, terminated by a denſe umbel of leaves and flowers. Leaves very many, ſpreading a little. Petiole jointed at the baſe, round, ſlender, villoſe, purpliſh, from one to three inches in length. Leaflets ſubſeſſile, emarginate, villoſe on both ſides and at the edges, ſoft, underneath dotted and having roundiſh yelloviſh ſcattered ſpots viſible in the microſcope, half an inch long. Scapes ſeveral, jointed at the baſe, almoſt the length of the leaves, round, hirſute, purpliſh, upright; bractes alternate, approximating at top. Calycine leaflets linear-lanceolate, acute, hirſute, ciliate, erect, purpliſh. Corolla ſeveral times as long as the calyx: claws erect, yellow: borders obovate, rounded, wide, ſpreading very much, ſnow-white within, whitiſh without. Filaments connate at the baſe: interior equal, hirſute with capitate hairs thinly ſet: exterior ſmooth. Anthers incumbent, yellow. Germ very ſhort, pale greeniſh yellow, hirſute at top. Styles hirſute with ſimple hairs [p].

56. Stipe about three inches long, frequently with a leaf or two on it. Petiole about three inches long. Leaflets ſomewhat of a hoary green. Calycine leaflets green, with the ends often ſpreading. Corolla five times as long as the calyx, yelloviſh at bottom, the reſt white: claws twice as long as the calyx. Interior filaments ſhorter than the claws of the corolla. Germ oblong, very hirſute at top and obſcurely callous.

It differs from the preceding in having the interior filaments unequal, and the exterior filaments not ſmooth, but hirſute with capitate hairs, and the ſtyles very ſhort [q].

57. Stipe ſtanding out, round, filiform, appearing ſomewhat villoſe in the microſcope, angular-grooved, one or two inches in length, having frequently a leaflet on it, terminated by an umbel of leaves and flowers. Leaves ſeveral. Petiole wide at the baſe, embracing, ſtriated, appearing villoſe in the magnifier. Leaflets ſubſeſſile, emarginate, converging, ciliate at the edges with diſtant hairs, underneath towards the edges having one row of roundiſh calluſes, a third part of an inch in length. Scapes few, obſcurely villoſe in the microſcope, erect, an inch and half long; with alternate, lanceolate, acute, erect bractes at top. Calycine leaflets lanceolate, acute, ciliate with a few hairs above, in other parts ſmooth, pale, underneath below the tip having two oblong yellow calluſes. Corolla three times as long as the calyx, ſubcampanulate; claws yellow: borders obovate, rounded, purple, ſpreading. Filaments connate at the baſe, wholly ſmooth: interior equal. Anthers oblong, incumbent, yellow. Germ ſtreaked with red. Styles hirſute with ſimple hairs below and capitate hairs above [r].

58. Bulb ovate, with a brown ſkin, leſs than a pea. Stipe partly under and partly above ground, from half an inch to two inches in length, filiform, ſmooth, the ſhorter upright, the longer procumbent, ſometimes leafleſs, ſometimes having a few leaves at the baſe or at top, terminated by a denſer umbel of leaves. Leaves ſeveral, ſpreading and erect. Petiole not jointed at the baſe, filiform, ſmooth, about an inch long. Leaflets ſubſeſſile, emarginate, dotted and green on both ſides, ſmooth except that they have ſometimes a hair or two at the back, about four lines in length, without any callus. Scape ſingle, jointed at the baſe, round, ſmooth, the length of the leaves, weak, green, with bractes at top, alternate, pale, having orange-coloured calluſes near the tip of the back. Calycine leaflets lanceolate-oblong, blunt, ſmooth, concave, upright, pale green, with two oblong orange calluſes on the tip of the back. Corolla three times as long as the calyx, bell-ſhaped: claws erect, yelloviſh: borders obovate, rounded, ſpreading very much, whitiſh violet. Filaments united at the baſe, ſmooth: interior unequal: exterior equal. Anthers oblong, incumbent, yellow. Germ oblong, ſmooth, pale. Styles ſmooth [s].

[n] Hort. kew. [o] Smith ic. rar. [p] Jacquin. [q] Idem. [r] Idem. [s] Idem.

59. Bulb oval, an inch long, covered with a black hard ſkin. Stipe ſtanding out, one or two inches in length, ſcaly, round, the thickneſs of a pigeon's quill, purpliſh, ſomewhat villoſe, erect, terminated by a denſe umbel of leaves and flowers. Leaves very many, ſpreading out in a ring. Petiole jointed at the baſe, round, about two inches in length, villoſe, greeniſh or reddiſh. Leaflets ſubſeſſile, hirſute on both ſides and at the edges, dotted and green on both ſides, half an inch long or more, the middle one often emarginate, the ſide ones quite entire. Scapes ſeveral, jointed at the baſe, round, ſomewhat villoſe, pale, almoſt upright, ſometimes longer, ſometimes ſhorter than the leaves, with oppoſite jointed bractes above the middle. Calycine leaflets lanceolate, bluntiſh, hirſute, ciliate, pale green with whitiſh edges, having generally below the tip one or two roundiſh orange ſpots, upright. Corolla ſeveral times longer than the calyx: claws upright, ſulphur-coloured; borders wide, rounded, ſnow-white within, ſomewhat ſulphur-coloured without, one ſide being variegated with red dots, ſpreading very much. Filaments connate at the baſe: interior toothletted, equal, hirſute with capitate hairs; the toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale yellowiſh green, hirſute at top, callous. Styles hirſute with ſhort capitate hairs mixed with a few long ſimple ones.

Jacquin doubted a long time whether this was any thing more than a variety of the next ſpecies: but the conſtant difference in the equal calycine leaflets, and the leaves never being waved, induced him at length to conſider it as a diſtinct ſpecies [t].

60. Bulb equal, an inch long, with a blackiſh-brown ſkin. Stipe from one to three inches long, almoſt upright, green or browniſh, ſlightly pubeſcent, leafleſs but having lanceolate, acuminate, ferruginous, ciliate ſcales, terminated by an umbel of leaves and flowers. Leaves ſeveral, almoſt upright or ſpreading a little. Petiole hirſute, from one to three inches long. Leaflets more or leſs waved, very ſeldom wholly flat, an inch long, rounded at the tip, having roundiſh dirty yellow dots ſcattered over them underneath, ſcarcely viſible even with a magnifying glaſs: the middle one ſlightly emarginate, and ſomewhat longer than the lateral ones, which are quite entire. Scapes longer than the leaves, pale or purpliſh: bractes below the middle. Calycine leaflets oblong, blunt, green above, below having blood-red ſpots, variegated on the back with roundiſh, yellow, ſcattered ſpots; one of them is larger and ſpatulate. Corolla five times as long as the calyx: claws ſhort, yellow: borders very wide, long, white with one ſide of the back dotted with purple. In other circumſtances it agrees with the preceding, except in thoſe pointed out before [u].

61. Bulb oval, covered with a black hard ſkin, an inch long. Stipe ſubterraneous, ſcaly above, an inch and more in length, terminated by a denſe umbel of leaves and flowers, under which is frequently another umbel or two that is leſs denſe. Leaves very many, ſpreading. Petiole jointed at the baſe, round, hirſute, two or three inches long. Leaflets ſubſeſſile, dotted, villoſe at the edges; the upper ſurface alſo villoſe, and green with duſky blood-red ſpots; the lower ſurface ſmooth and almoſt wholly blood-red; about half an inch long, rounded; the middle one wedgeform-obovate or rather roundiſh, quite entire or ſlightly emarginate, the lateral ones oblong and quite entire. Scapes ſeveral, jointed at the baſe, round, ſomewhat villoſe, erect, pale, ſlender, four inches long, with oppoſite jointed bractes above the middle. Calycine leaflets lanceolate, blunt, hirſute, ciliate, erect, green with a roſe-coloured baſe, ſpotted along the middle of the back in two orange-coloured interrupted lines, ſometimes entirely wanting. Corolla large: claws erect, twice as long as the calyx, yellow within: borders white with one ſide of the back fleſh-coloured, rounded, wide, ſpreading very much. Filaments connate at the baſe: interior toothletted, equal, ſmooth at top, in the other parts hirſute with capitate hairs, except the toothlets which are ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ hirſute at top, callous. Styles hirſute with hairs that are ſometimes all capitate or all ſimple, ſometimes mixed but always ſhort [v].

62. Bulb ovate, covered with a black hard ſkin, twice as large as a hazel nut. Stipe one or two, ſtanding out, round, the thickneſs of a pigeon's quill, from one to three inches long, erect or procumbent, villoſe, ſcaly, leafleſs, purpliſh, weak, terminated by a denſe umbel of leaves and flowers. Leaves very many, ſpreading in a ring. Petiole jointed at the baſe, round, pale green or purpliſh, one or two inches long, hirſute with capitate hairs. Leaflets ſubſeſſile, dotted, villoſe at the edges and on the back with capitate hairs, on the upper ſurface green with a few ſimple hairs, underneath commonly blood-red, blunt, quite entire, from half an inch to an inch in length, the middle one wedge-obovate, the ſide ones oblong. Scapes ſeveral, jointed at the baſe, the length of the leaves or much longer, round, whitiſh, villoſe with capitate hairs, almoſt upright or ſpreading; bractes oppoſite, jointed, below the middle. Calycine leaflets lanceolate, bluntiſh, pale green, villoſe with capitate hairs at the edges and a few on the back, erect, often purpliſh at the baſe, below the tip frequently having one or two roundiſh yellow ſpots, but theſe are not ſeldom wanting. Corolla ſeveral times longer than the calyx, ſmooth, wide, dirty white on the outſide, within yellow and upright at the baſe, the reſt white, blunt and ſpreading very much. Filaments connate at the baſe; interior toothletted, equal, hirſute with capitate hairs, as are alſo the toothlets: exterior ſmooth. Anthers incumbent, yellow. Germ hirſute at top, callous. Styles very hirſute with ſimple blunt hairs [w].

63. Bulb ovate-roundiſh, covered with a black ſkin, larger than a hazel nut. Stipe commonly wholly ſubterraneous, having one or two ſcales at top, ſhort, leafleſs, round, almoſt as thick as a pigeon's quill, terminated by a denſer umbel of leaves and flowers. Leaves ſeveral, erect or ſpreading. Petiole jointed at the baſe, grooved in front, compreſſed a little, hirſute, one or two inches long. Leaflets ſeſſile, quite entire or ſlightly emarginate, about an inch long, villoſe at the edges, green on both ſides, hirſute and ſlightly dotted above, paler, much dotted, and leſs hirſute above. Scapes ſeveral, jointed at the baſe, roundiſh, villoſe, pale, longer than the leaves, almoſt upright; bractes oppoſite, jointed, about the middle. Calycine leaflets lanceolate, acute, hirſute, pale green, ciliate, erect. Corolla ſeveral times longer than the calyx: claws erect, three times as long as the calyx, dirty yellow: borders very wide, rounded, ſpreading very much, yellow within, very pale yellow on the outſide, with one ſide of the back having blood-red dots. Filaments united at the baſe: interior toothletted, equal, thinly hirſute with capitate hairs; the toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale yellowiſh green, cloſely hirſute at top, callous. Styles very hirſute with capitate hairs.

β. Bulb oval, an inch long, covered with a black hard ſkin. Stipe either wholly ſubterraneous or ſtanding out a little, ſcaly, leafleſs, round, whitiſh, about an inch long, upright, thinner than a pigeon's quill. Leaves very many, ſpreading out in a ring. Petiole round, villoſe. Leaflets ſubſeſſile, dotted, villoſe and green on both ſides, ciliate, about half an inch long; the middle one ſubemarginate, the ſide ones rounded and quite entire, appearing to have many obſcure calluſes when examined by a magnifier. Scapes whitiſh, upright, twice as long as the leaves. Calycine leaflets villoſe, erect except that they are ſometimes ſpreading at the tips, pale green with the lower edges having dark blood-red dots, deeper green above with yellow calluſes more or leſs ſcattered over them. Corolla five times as long as the calyx: claws yellow, twice as long as the calyx: borders white with one ſide of the back blood-red dotted and ſomewhat villoſe. Filaments connate at the baſe: interior ſmooth above, in other parts very hirſute with capitate hairs; the

[t] Jacquin. [u] Idem. [v] Idem. [w] Idem.

toothlets

toothlets alſo hirſute: exterior ſmooth. In other reſpects agreeing with the other [a].

64. Bulb oval, an inch and half long, covered with a black hard ſkin. Stipe partly under, partly above ground, ſcaly, round, about an inch high, upright, leafleſs, terminated by a denſe umbel of leaves and flowers. Leaves very many, erect or ſpreading a little. Petiole jointed at the baſe, round, ſlender, green, hirſute, about two inches in length. Leaflets ſubſeſſile, hirſute at the edges and on the upper ſurface, dotted and ſmooth on the back, rounded at the end, half an inch long, ſometimes all unſpotted, ſometimes duſky ſpots ſcattered over the face of ſome of them, or even of all; the middle one obovate, emarginate, the ſide ones oblong and quite entire. Scapes ſeveral, jointed at the baſe, round, ſlender, whitiſh, ſomewhat villoſe, double the length of the leaves; with oppoſite, jointed bractes about the middle. Calycine leaflets lanceolate, bluntiſh, hirſute, ciliate, pale green, with from one to four roundiſh orange ſpots below the tip, upright. Corolla five times as long as the calyx: claws erect, pale yellow: borders rounded, ſpreading very much, white with one ſide of the back purpliſh. Filaments connate at the baſe: interior toothletted, equal, ſmooth above, in other parts very minutely hirſute, as are alſo the toothlets: exterior ſmooth. Anthers incumbent, yellow. Germ pale greeniſh yellow, hirſute at top, callous. Styles hirſute with ſimple hairs [b].

65. Bulb ſubovate, with a blackiſh-brown ſkin, leſs than an inch in length. Stipe ſtanding out, ſcaly, leafleſs, round, the thickneſs of a pigeon's quill, villoſe, almoſt upright, about an inch in length, terminated by a denſer umbel of leaves and flowers. Leaves ſeveral, erect or ſpreading a little. Petiole jointed at the baſe, round, grooved in front, hirſute, about two inches long. Leaflets blunt, generally quite entire, villoſe at the edges, on both ſides green, villoſe, and appearing dotted in the magnifier, ſubſeſſile. Scapes ſeveral, jointed at the baſe, hirſute, round, pale, higher than the leaves; with oppoſite jointed bractes below the middle. Calycine leaflets lanceolate, acute, pale green, ciliate, hirſute, erect. Corolla ſeveral times longer than the calyx: claws erect, twice as long as the calyx, pale yellow: borders wide, rounded, ſpreading very much, yellow within, pale whitiſh yellow without, with one ſide of the back blood-red dotted. Filaments connate at the baſe: interior toothletted, equal, thinly and very minutely hirſute with capitate hairs; the toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ pale greeniſh yellow, hirſute above, callous. Styles hirſute with ſimple hairs [b].

66. Bulb ovate-acuminate, with a blackiſh-brown ſkin, about an inch in length. Stipe partly under, partly above ground, round, villoſe, the thickneſs of a pigeon's quill, green, procumbent, ſomewhat ſcaly, an inch and half long, leafleſs, terminated by a denſe umbel of leaves and flowers. Leaves very many, almoſt upright and ſomewhat ſpreading. Petiole jointed at the baſe, roundiſh, villoſe, two inches long. Leaflets ſeſſile, very villoſe and ſoft on both ſides and at the edges, blunt, quite entire, almoſt an inch long, having roundiſh yellowiſh dots viſible only with a glaſs, ſcattered over the under ſurface. Scapes many, jointed at the baſe, roundiſh, villoſe, whitiſh, from four to ſix inches in length, upright at bottom, the reſt flaccid: bractes oppoſite, jointed, above the middle. Calycine leaflets inverſely wedge-ſhaped, blunt, ciliate, hirſute, upright with ſpreading tips, green with pale edges, and tinged a little with purple underneath, below the tip marked with from one to four roundiſh orange ſpots. Corolla five times as long as the calyx: claws erect, yellow on both ſides, twice as long as the calyx: borders very wide, rounded, ſpreading very much, white on both ſides with one ſide of the back blood-red dotted and obſcurely villoſe. Filaments connate at the baſe: interior toothletted, equal, ſmooth above, in other parts hirſute with thinly ſcattered capitate hairs, except the toothlets, which are ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ pale yellowiſh green, hirſute at top, callous. Style hirſute with ſimple hairs.

O. exaltata has always long ſlender ſcapes ſtrictly upright, and ſpotted leaves. *Rubreflava* and *flaccida* have always green unſpotted leaves; and the former of theſe has yellow flowers on ſhorter upright ſcapes; the latter has white flowers on very long flaccid ſcapes. If theſe differences be not thought ſufficient to diſtinguiſh the ſpecies, the three laſt may be conſidered only as varieties [c].

67. Bulb ovate, with a blackiſh ſkin, half the ſize of a hazel nut. Stipe ſubterraneous, an inch long, terminated by an umbel of leaves and flowers. Leaves ſeveral. Petiole jointed at the baſe, roundiſh, villoſe, purpliſh green, three or four inches long, erect or ſpreading a little. Leaflets always green on both ſides, ſubſeſſile, ſomewhat veined, villoſe at the edges, above ſmooth and manifeſtly dotted when examined by a magnifier, wholly pubeſcent underneath. Scapes very many, jointed at the baſe, red, round, villoſe, from ſix to nine inches long, almoſt upright at bottom, and thence more or leſs reclining; with alternate bractes below. Calycine leaflets lanceolate, ſharpiſh, green with one or two orange ſpots at top, which however are often wanting; hirſute, ciliate either with all the hairs ſimple, or the lower ones capitate and very ſhort. Corolla large: claws upright, yellow on both ſides: borders longer than the claw, wide, rounded, ſpreading very much, white on both ſides with a ſuffuſion of fleſh-colour within above the claws, and with one ſide of the back reddiſh and ſomewhat villoſe. Filaments connate at the baſe: interior toothletted, equal, ſmooth at the top, the reſt very hirſute with capitate hairs; with the toothlets hirſute in the ſame manner: exterior alſo hirſute, only more ſparingly. Anthers incumbent, yellow. Germ pale green, hirſute at top. Styles hirſute at the baſe with ſimple hairs, in other parts quite ſmooth.

β. The variety with red flowers has the bulb the ſize of a hazel nut. Stipe partly under, partly above ground and ſcaly. Leaves very many. Petiole ſomewhat hirſute, pale green, two or three inches long. Leaflets ſometimes emarginate, on both ſides green and dotted, underneath pubeſcent at the midrib and principal veins, half or three quarters of an inch in length. Scapes roundiſh, pale, very thinly hirſute, almoſt upright, a little longer than the leaves. Calycine leaflets green with the edges blood-red at bottom. Hairs ſometimes capitate, ſhort, and a very few among the lower cilias. Corolla ſeveral times longer than the calyx: borders the ſame length with the claws, red on both ſides, except that one ſide of the back is dirty yellow and ſomewhat villoſe. In other reſpects it agrees with the preceding [c].

68. Bulb ovate, acute, ſmall, looſe. Stipe ſubterraneous, an inch and half long. Leaves ſeveral, in a ring. Petiole round, grooved in front, thinly hirſute, blood-red, about two inches in length. Leaflets ſeldom and ſlightly emarginate, dotted on both ſides, of a darker green on the upper ſurface, on the lower ſomewhat hirſute with decumbent hairs thinly ſpread, ſhining, ſometimes green, ſometimes blood-red in whole or in part, about half an inch in length, thickiſh. Scapes the length of the petioles, pale with a tinge of purple, round, ſmooth or with very few hairs, upright. Calycine leaflets lanceolate or ovate, green or purpliſh with duſky-orange lines, thinly villoſe, ciliate at the edges, with long ſimple hairs at top, in other parts with ſhort capitate hairs. Corolla very large: claws yellow on both ſides and upright: borders wedge-ſhaped, longer than the claws, truncated, ſpreading very much, white with one ſide of the back reddiſh and villoſe, together with the claws an inch and half long. Germ conical, the whole quite ſmooth. Styles hirſute with ſimple hairs at the baſe only, in other parts quite ſmooth.

This bears a great affinity to *O. variabilis*, differing chiefly in having the leaflets commonly blood-red underneath, whereas in that they are always green [c].

[a] Jacquin. [b] Idem. [c] Idem. [d] Idem. [e] Idem.

69. Bulb ovate, with a blackiſh-brown ſkin, from the ſize of a hazel nut to twice that bigneſs. Stipe ſhortly ſubterraneous, then ſtanding out, from three to five inches long, round, purple, ſmooth, without ſcales, the thickneſs of a pigeon's quill or thicker, wholly procumbent, branched, brittle with a central tough fibril, thickened at the tip, and from this terminated by a very cloſe and elegant umbel of leaves and flowers, and finally denſely bulb-bearing from the ſame. Leaves very numerous, ſpreading every way. Petiole jointed at the baſe with a two-toothed joint, round, pale green, ſmooth, three or four inches long. Leaflets ſubſeſſile, quite entire, half an inch long, ſmooth and dotted on both ſides, ſmooth at the edges, above deep green, underneath paler and ſhining with ſilvery dots, ſome of them, when far advanced, purple with the like dots but of a golden colour, ſomewhat fleſhy. Scapes ſeveral, jointed at the baſe without toothlets, compreſſed, grooved on one ſide, ſmooth, pale purple, longer than the leaves, almoſt upright, with alternate, diſtant, oblong, blunt, concave, ſmooth, erect bractes, frequently purpliſh, above the middle. Calycine leaflets oblong, blunt, upright, ſmooth only ciliate at the edges with a very few ſimple hairs viſible in a glaſs, dirty greeniſh pale yellow with red edges. Corolla four times as long as the calyx, ſmooth: claws upright, yellow, a little longer than the calyx; borders very wide, rounded, ſpreading very much, roſe-coloured with one ſide of the back dirty ſulphur-coloured. Filaments connate at the baſe: interior toothleſs, equal, ſmooth at top, in other parts hirſute with capitate hairs: exterior hirſute below with ſimple long hairs thinly ſet, above with ſhorter capitate hairs; or quite ſmooth. Anthers incumbent, yellow. Styles hirſute with capitate hairs. Stigmas very cloſely pencilled [f].

70. Bulb ovate, looſe, ſmall, looſely incloſed in a ſkin, from three to ſix times the ſize of the bulb. Stipe ſubterraneous, from one to three inches long, round, ſlender, often bulbiferous, terminated by a denſe umbel of leaves and flowers. Leaves very many, ſpreading or lying on the ground. Petiole jointed at the baſe, denſely villoſe, pale green, from one to three inches long. Leaflets ſeſſile, quite entire, villoſe at the edges, quite ſmooth above, underneath ſomewhat hirſute and muſh dotted, always green on both ſides without any other colour, half an inch and more in length. Scapes ſeveral, jointed at the baſe, round, ſomewhat villoſe, pale green, almoſt upright, longer than the leaves; bractes ſublinear, ſharp, villoſe, approximately alternate at bottom. Calycine leaflets lanceolate, acute, hirſute, ciliate with ſimple hairs, green with blood-red ſpots at the edges, erect. Corolla ſeveral times longer than the calyx, bell-ſhaped: claws erect, yellow: borders obovate, wide, very blunt, generally longer than the claws, very deep purple on both ſides, with one ſide of the back dirty yellow and ſomewhat villoſe. Filaments united at the baſe: interior equal, ſmooth at top, the reſt, with the toothlets, very hirſute with capitate hairs; exterior ſmooth. Anthers oblong, incumbent, yellow. Germ pale green, the whole ſmooth. Styles very hirſute all over with capitate hairs [g].

According to Linnæus, the leaflets are obcordate, obſoletely emarginate, ſmooth even underneath, very finely ciliate. Scapes the length of the leaves. This does not agree with Jacquin's figure or deſcription.]

Mr. Miller ſays, the leaflets are roundiſh, large, hairy, and but little indented at the top, ſtanding upon long ſlender foot-ſtalks, ariſing from a thick ſhort ſtalk which adheres to the root. He adds, that ſome earth that came to England with plants from the Cape of Good Hope was full of it. [In 1690, it was cultivated in the royal garden at Hampton Court [h].

71. Bulb leſs than a hazel nut, with a blackiſh-brown ſkin. Stipe about an inch long, terminated by a looſe umbel. Leaves ſeveral. Petiole grooved in front, pale purple, thinly villoſe, three or four inches long, upright or ſpreading. Leaflets ſubſeſſile, often ſlightly emarginate, ſmoothiſh above, half or two thirds of an inch in length. Scapes thinly hirſute, purpliſh, the length of the leaves. Some of the hairs of the calyx towards the bottom are often ſhort and capitate. Borders of the corolla rounded, the length of the claws, ſpreading very much, white with one ſide of the back yellow and ſomewhat villoſe. Germ hirſute at top. Styles very hirſute with capitate and ſimple hairs. It is ſo nearly allied to the preceding, that it may perhaps be nothing more than a variety [i].

72. Bulb oval, with a black hard ſkin, an inch long. Stipe ſubterraneous, an inch in height, thick, terminated by a denſe umbel of leaves and flowers. Leaves very many, proſtrate in a ring. Petiole jointed at the baſe, villoſe, very much compreſſed, white or purple, from one to three inches long. Leaflets ſubſeſſile, ſometimes but ſeldom ſlightly emarginate, ſomewhat villoſe at the edges, otherwiſe ſmooth on both ſides, above glaucous green and appearing dotted when magnified, underneath manifeſtly dotted, and uſually more or leſs blood-red, near an inch in length. Scapes ſucceſſively very many, jointed at the baſe, compreſſed a little, ſomewhat villoſe, purple, ſcarcely an inch in height, erect or aſcending, after flowering ſtiffly proſtrate; bractes ſubalternate about the middle. Calycine leaflets, lanceolate, acute, ſomewhat villoſe, ciliate, erect, purple. Corolla four times as long as the calyx, ſmooth: claws upright, yellow: borders white, rounded, ſpreading very much. Filaments connate at the baſe: interior equal, ſpreading a little at the tip, ſparingly hirſute, together with the toothlets, with capitate hairs: exterior ſmooth. Anthers incumbent, yellow. Germ pale green, hirſute above. Styles hirſute with ſimple hairs at the baſe [k].

73. Bulb ovate, an inch long, covered with a blackiſh ſkin. Stipe ſubterraneous, an inch in height, terminated by a ſtiffiſh umbel of leaves and ſcapes. Leaves very many, ſpreading in a ring. Petiole jointed at the baſe, roundiſh, ſomewhat hirſute, pale, two or three inches long. Leaflets ſubſeſſile, ſometimes but ſeldom ſlightly emarginate, on both ſides dotted, green and ſmooth, underneath thinly hirſute at the midrib only, villoſe at the edges, veined, about an inch in length. Scapes ſeveral, jointed at the baſe, roundiſh, thinly hirſute, pale purple, aſcending or almoſt upright, about the ſame length with the leaves; bractes alternate and hirſute at bottom. Calycine leaflets lanceolate, acute, hirſute, green, unſpotted, ciliate with long ſimple hairs and ſhort capitate hairs mixed, erect, half turned back after the corolla falls. Corolla four times as long as the calyx: claws erect, yellow: borders wide, rounded, the length of the claws, ſpreading very much, white with one ſide of the back ſulphur-coloured and appearing villoſe in the magnifier. Filaments connate at the baſe: interior toothletted, equal, together with the toothlets very hirſute with capitate hairs: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale green, hirſute at top. Styles very hirſute with ſhort capitate hairs and a very few long ſimple ones among them [l].

74. Bulb oval, with a blackiſh ſkin, leſs than an inch in length. Spike ſubterraneous, an inch long, ſcaly at top, terminated by an umbel of leaves and flowers. Leaves very many, ſpreading in a ring. Petiole jointed at the baſe, roundiſh, hirſute, more or leſs red, from two to four inches in length. Leaflets ſubſeſſile, ſometimes but ſeldom ſlightly emarginate, denſely villoſe at the edges, the upper ſurface green, ſmooth on both ſides, the under ſurface of a very deep blood red and ſhining from the firſt, almoſt an inch in length. Scapes ſeveral, jointed at the baſe, compreſſed a little, very cloſely hirſute, pale purple, erect, ſhorter than the leaves; bractes ſubalternate below. Calycine leaflets ovate, ſharpiſh, erect, green with a purple baſe, hirſute, ciliate with ſimple hairs. Corolla five times as long as the calyx, elegant: claws erect, dirty yellow: borders wide, rounded, ſpreading very much, of a very deep roſe-colour with one ſide of the back dirty yellow and villoſe, longer than the claws. Filaments connate at the baſe: interior toothletted, equal, very

[f] Jacquin. [g] Idem. [h] Hort. kew. [i] Jacquin. [k] Idem. [l] Idem.

hirſute with capitate hairs, and here and there one or two on the toothlets: exterior ſmooth. Anthers incumbent, yellow. Germ pale green, hirſute at top. Styles very hirſute with ſhort capitate hairs mixed with a very few long ſimple ones [m].

75. Bulb oval, with a blackiſh ſkin, leſs than an inch in length. Stipe ſubterraneous, about an inch and half in height, terminated by an umbel of leaves and flowers. Leaves ſeveral, in a ring. Petiole jointed at the baſe, roundiſh, hirſute, more or leſs red, from two to three inches long. Leaflets ſubſeſſile, ſometimes but ſeldom emarginate, having cloſe and long villoſe hairs at the edges, above green and ſmooth, underneath having ſhining dots and appearing ſomewhat rough-haired in the magnifier; about an inch in length. Scapes ſeveral, jointed at the baſe, compreſſed a little, ſomewhat hirſute, pale purple, upright, ſhorter than the leaves; having ſubalternate bractes below. Calycine leaflets ovate, ſharpiſh, erect, green, unſpotted, hirſute, ciliate with ſimple hairs. Corolla four times as long as the calyx: claws erect, yellow, a little exceeding the calyx: borders obovate, rounded, wide, ſpreading very much, ſmooth, white with one ſide of the back roſe-coloured. Filaments connate at the baſe: interior toothletted, equal, very hirſute with capitate hairs; toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ pale green, hirſute above and callous. Styles very hirſute with ſhort capitate hairs and a very few long ſimple ones mixed with them [n].

76. Bulb ovate-roundiſh, with a black hard ſkin, almoſt the ſize of a walnut. Stipe ſtanding out, extremely ſhort, terminated by an umbel of leaves and flowers. Leaves ſeveral, ſpreading in a ring. Petiole jointed at the baſe, about an inch and half long, compreſſed a little, thickiſh, woolly with white villoſe hairs. Leaflets ſubſeſſile, obverſely triangular, half an inch in length and breadth, ſilky-ciliate at the edges, with veins running over them that are preſſed in above and protuberant beneath: on the upper ſurface appearing dotted in the magnifier, ſilky and ſomewhat hoary; on the back violet with pale veins, and cloſely ſilky; thickiſh and ſoft to the touch like thoſe of Marſh Mallow. Scapes ſeveral, jointed at the baſe, round, denſely hirſute with whitiſh villoſe hairs, erect, three or four inches in height: with oppoſite jointed bractes above the middle. Calycine leaflets lanceolate, ſharpiſh, villoſe, erect, green, ciliate with ſilky villoſe hairs. Corolla ſeveral times longer than the calyx: claws erect, twice as long as the calyx, yellow: borders broad wedge-form, rounded, the length of the claws, ſpreading very much, violet-purple, with one ſide of the back pale and ſomewhat villoſe. Filaments connate at the baſe: interior appendicled, equal, hirſute with capitate hairs; the toothlets ſmooth; exterior ſmooth. Anthers incumbent, yellow. Styles hirſute with ſimple hairs [o].

77. Bulb oval, covered with a blackiſh hard ſkin, an inch and more in length. Stipe ſubterraneous, about an inch long, terminated by a denſe umbel of leaves and flowers. Leaves very many, in a ring. Petiole jointed at the baſe, roundiſh, hirſute, purple, from one to three inches long. Leaflets ſubſeſſile, very much dotted on both ſides, villoſe at the edges, dark green on the upper ſurface, ſomewhat netted with hirſute raiſed veins, in other parts ſmooth; on the lower ſurface ſomewhat villoſe, blood-red, with golden ſhining dots ſcattered over it, about half an inch in length and breadth. Scapes ſeveral, jointed at the baſe, round, pale, ſomewhat hirſute, almoſt upright, the length of the leaves; with alternate bractes at bottom. Calycine leaflets ovate, bluntiſh, ciliate at the edges with club-ſhaped hairs at bottom mixed with others that are ſhorter, in other parts ſmooth or appearing villoſe only with a magnifier, very pale green with the edges red to the middle, and orange lines at the tip on both ſides, erect but turned back at the end. Corolla wholly ſulphur-coloured, ſeveral times longer than the calyx. Petals wedge-ſhaped, rounded, erect as far as the middle and yellow within, thence ſpreading very much. Filaments connate at the baſe: interior equal, thinly hirſute with ſimple hairs: exterior ſmooth. Anthers incumbent, yellow. Styles hirſute with ſimple hairs [p].

78. Stipe filiform, ſubmerſed, of an indeterminate length, leafleſs but having a few ſcales, terminated by an umbel of leaves and flowers floating on the ſurface of the water. Leaves ſeveral. Petiole widening at the baſe, but not jointed, ſomewhat villoſe, ſcarcely a quarter of an inch in length. Leaflets ſubſeſſile, green above, in the magnifier appearing dotted towards the edges, and obſcurely villoſe: underneath glaucous, ſmooth and undotted; ſcarcely the length of the petioles. Calycine leaflets oblong, blunt, ſmooth, the two inner ones ſhorter. Corolla twice as long as the calyx, white. Filaments connate at the baſe, wholly ſmooth: interior equal. Germ a little villoſe at top. Styles ſmooth [q].

79. Bulb oval or obovate, with a black hard ſkin, almoſt an inch in length. Stipe ſubterraneous, one or two inches long, terminated by a denſe umbel of leaves and flowers. Leaves numerous, villoſe on both ſides and at the edges. Petioles roundiſh, one or two inches in length, dirty purple, jointed at the baſe. Leaflets ſubſeſſile, dotted on both ſides, above dirty deep green with oblong livid ſpots, underneath commonly all livid, ſcarcely half an inch in length. Scapes very many, round, ſomewhat villoſe, pale purple, of different lengths, jointed at the baſe; with oppoſite jointed bractes at bottom. Calycine leaflets oblong, blunt, erect, hirſute with ſimple hairs on the back and at the edges, blood-red on the back with the middle of the diſk green and marked above with two longitudinal orange lines. Corolla ſix times as long as the calyx: claws upright, ſhort, yellow within, whitiſh on the outſide: borders wide, rounded, ſpreading very much, white within, dotted with red without on one ſide. Filaments connate at the baſe: interior ſmooth at top, in other parts hirſute with very minutely capitate hairs: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, very hirſute at top, pale green, callous. Styles hirſute with ſimple hairs, underneath on the neck or below the ſtigma having a convex, ſhining red-orange *ſtruma* or gland [r].

80. Bulb ovate or oval, with a blackiſh ſkin, half the ſize of a hazel nut. Stipe ſubterraneous, about an inch long, terminated by a looſe umbel of leaves and flowers. Leaves ſeveral, villoſe all over on both ſides and at the edges. Petiole jointed at the baſe, round, ſlender, pale, from two to four inches in length. Leaflets ſubſeſſile, dirty green on both ſides, dotted underneath, never livid, ſcarcely half an inch long. Scapes ſeveral, jointed at the baſe, almoſt upright, appearing ſomewhat villoſe when magnified, longer than the leaves, whitiſh; with oppoſite jointed bractes at top. Calycine leaflets oblong, blunt, upright, denſely hirſute on the back and at the edges with ſimple hairs, green, with two orange lines underneath below the tip. Corolla wholly yellow: claws upright, twice as long as the calyx: borders rounded, wider, ſpreading very much. Filaments connate at the baſe: interior hirſute with capitate hairs, except the toothlets, which are ſmooth: exterior ſmooth. Anthers oblong, incumbent, yellow. Germ ovate, pale green, ſubhirſute at top, with a very few yellow calluſes. Styles hirſute with ſimple hairs [s].

81. Bulb deep in the ground. Stipe ſtanding out, cloſely woolly, with one or two woolly ſcales, about half an inch in length, terminating in an umbel of flowers and leaves. Leaves ſeveral, ſmall. Petiole hirſute, half an inch long. Leaflets ſeſſile, wide, with long thick villoſe hairs on both ſides and at the edges. Scapes ſeveral, very hirſute, from half an inch to two inches in length; with oppoſite, lanceolate-linear, acute, concave, villoſe, erect, jointed bractes above the middle. Calycine leaflets lanceolate, acute, hirſute, ciliate, erect. Corolla four times as long as the calyx, villoſe on the outſide, bell-ſhaped: claws erect, yellow: borders obovate, blunt, ſpreading, white. Filaments united at the baſe into a hirſute cylinder: interior hirſute with ſimple hairs; exterior hirſute in like manner,

[m] Jacquin. [n] Idem. [o] Idem. [p] Idem. [q] Idem, from Thunberg. [r] Jacquin. [s] Idem.

ther. Anthers ovate, erect, yellow. Germ hirſute. Styles alſo hirſute, yellow [a].

82. Bulb oval or ovate, half the ſize of a hazel nut, with a hard blackiſh variouſly angular ſomewhat ſtriated and wrinkled ſkin. Stipe ſubterraneous, about half an inch long, terminated by a thinner umbel of leaves and flowers. Leaves ſeveral. Petiole jointed at the baſe, ſlender, weak, round, ſomewhat villoſe, pale green or purple, from one to three inches long. Leaflets ſubſeſſile, ſmooth on both ſides and at the edges, dotted on both ſides, deep green above, bright purple underneath with ſhining golden dots, the third part of an inch in length and breadth. Scapes ſeveral, jointed at the baſe, round, ſomewhat villoſe with capitate hairs, almoſt upright, pale, a little longer than the leaves; with alternate bractes at top. Calycine leaflets ovate, ſharpiſh, erect, ſomewhat hirſute on the back and at the edges with capitate hairs, green with purple edges. Corolla ſix times as long as the calyx: claws erect, yellow: borders obovate, rounded, ſpreading very much, very pale fleſh-coloured. Filaments connate at the baſe; all, together with the tips of the teeth, hirſute with capitate hairs thinly ſet. Anthers incumbent, yellow. Germ pale green, hirſute at top. Styles ſmooth above, ſomewhat hirſute with ſimple hairs below [b].

83. Bulb deep in the ground. Stipe ſtanding out, villoſe, half an inch long, terminating in an umbel of leaves and flowers. Leaves ſeveral. Petiole hirſute, an inch long. Leaflets ſeſſile, hirſute on both ſides and at the edges, ſmall. Scapes ſeveral, villoſe, an inch and half long; with bractes at top, oppoſite, lanceolate, villoſe, jointed. Calycine leaflets oblong, rounded and blunt, ciliate, hirſute, erect. Corolla four times as long as the calyx, bell-ſhaped: claws erect, yellow: borders obovate, rounded, ſpreading very much, ſmooth, purple or variegated. Filaments connate at the baſe, ſmooth. Anthers oblong, incumbent. Germ roundiſh-ovate, hirſute at top. Styles hirſute with ſimple hairs [c].

84. Bulb ovate or oval, with a blackiſh-brown ſkin, half the ſize of a hazel nut. Stipe ſubterraneous, about an inch in length, terminated by a looſe umbel of leaves and flowers. Leaves ſeveral, the whole ſomewhat villoſe on both ſides and at the edges. Petiole jointed at the baſe, round, ſlender, from two to four inches in length, pale. Leaflets ſubſeſſile, dirty green on both ſides, dotted underneath and ſeldom livid, ſcarcely half an inch in length. Scapes ſeveral, jointed at the baſe, whitiſh, almoſt upright, appearing ſomewhat hirſute when magnified, longer than the leaves, ſometimes marked with red ſpots below the flower; with oppoſite jointed bractes at top. Calycine leaflets lanceolate, bluntiſh, upright, thinly hirſute underneath and at the edges with ſimple hairs, bloodred ſpotted below on the diſk of the back and marked with two yellow lines below the tip, in other parts pale green. Corolla wholly yellow: claws erect, twice as long as the calyx: borders rounded, wide, ſpreading very much. Filaments connate at the baſe: interior hirſute with capitate hairs; the toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, pale green with a few hairs and a few orange calluſes above. Styles hirſute with capitate hairs [d].

85. Bulb oval, with a blackiſh-brown hard ſkin, an inch long. Stipe ſubterraneous, ſcarcely an inch in length, terminated by a denſe umbel of leaves and flowers. Leaves very many, ſpreading in a ring. Petiole jointed at the baſe, roundiſh, thick, very hirſute, purple, from one to two inches in length. Leaflets dotted on both ſides, villoſe at the edges, ſomewhat firm and veined, ſmooth and dark green above, underneath blood-red with the upper margin cinereous-green, ſhining with golden dots, and appearing ſomewhat villoſe when magnified; the middle one frequently three quarters of an inch long and an inch wide. Scapes ſeveral, jointed at the baſe, round, pale, hirſute with thick hairs, almoſt upright or ſpreading a little, an inch and half long, more ſlender than the petioles; with alternate bractes about the middle. Calycine leaflets ovate, ſharpiſh, more cloſely ciliate at the edges with thick hairs, in other parts ſmooth or villoſe only in the magnifier, very pale green, having orange lines on each ſide at the tip, erect with the tips bent back. Corolla ſeveral times as long as the calyx: claws rolled up into a funnel, dirty white on the outſide, yellow within: borders wide, rounded, longer than the claws, ſpreading very much, white on both ſides. Filaments connate at the baſe: interior thinly hirſute with ſimple hairs: exterior ſmooth. Anthers incumbent, yellow. Styles very hirſute with ſimple hairs [e].

86. Bulb oval or ovate, with a blackiſh-brown hard ſkin, about an inch in length. Stipe ſubterraneous, very ſhort, terminated by an umbel of leaves and flowers. Leaves ſeveral, ſpreading in a ring. Petiole jointed at the baſe, roundiſh, very hirſute, purple, one or two inches long. Leaflets dotted on both ſides, villoſe at the edges, ſomewhat firm and veined, ſmooth and dark green above, underneath deep bright blood-red, ſhining with golden dots, and ſomewhat villoſe when magnified, about half an inch in length and breadth. Scapes ſeveral, very ſhort, ſcarcely half an inch long, jointed at the baſe, round, hirſute with thick hairs, almoſt upright, pale; with alternate bractes above the middle. Calycine leaflets ovate, bluntiſh, thinly ciliate at the edges with thick hairs, in other parts ſmooth, or when examined by a glaſs ſomewhat villoſe, very pale green with the edges red below, and orange lines at each ſide at the tip, upright except at the tips, which are turned back. Corolla ſeveral times longer than the calyx: claws rolled up in form of a funnel, whitiſh on the outſide, yellow within: borders obovate, rounded, the length of the claws, ſpreading very much, white on both ſides, with a bluſh of carnation within above the baſe. Filaments connate at the baſe: interior equal, hirſute with capitate hairs: exterior ſmooth. Anthers incumbent, yellow. Germ oblong, ſomewhat villoſe above, pale green. Styles very hirſute with moſt minutely capitate hairs [f].

87. Bulb oval or ovate, with a blackiſh ſkin, half the ſize of a hazel nut. Stipe ſubterraneous, about an inch in length, terminated by a looſe umbel of leaves and flowers. Leaves ſeveral. Petiole jointed at the baſe, round, ſlender, villoſe, pale green, from two to three inches in length. Leaflets ſubſeſſile, dirty green and dotted on both ſides, villoſe on the back and at the edges, ſmooth on the upper ſurface, ſcarcely half an inch in length and breadth. Scapes ſeveral, with a longer joint than ordinary at the baſe, manifeſtly villoſe, almoſt upright, pale, about the ſame length with the leaves; with oppoſite jointed bractes at top. Calycine leaflets oblong, bluntiſh, erect, thinly hirſute on the back and at the edges with ſimple hairs, pale green, with two yellow lines underneath below the tip, and ſometimes variegated at bottom with bloody ſpots. Corolla wholly yellow: claws upright, twice as long as the calyx: borders rounded, wider, ſpreading very much. Filaments connate at the baſe: interior equal, hirſute with capitate hairs; toothlets ſmooth: exterior ſmooth. Anthers incumbent, yellow. Germ pale green, ſmooth, callous at top. Styles very hirſute with capitate hairs [g].

88. Bulb in the young plant ovate, covered with a brown ſkin, twice the ſize of a pea. The root in the mature plant conſiſts of ſeveral legs ſlenderly fuſiform, terminating in a long fibre, round, the thickneſs of a reed and more, ſome inches in length, fleſhy, brittle, pale, ſomewhat pellucid and ſweet. Stipes very many, herbaceous, round, the thickneſs of a pigeon's quill or even of a reed, thick, green or purpliſh brown, a foot and half high, upright but ſo weak as not to be able to ſupport themſelves without aſſiſtance, at the baſe and origin of the branches having an ovate-acuminate ſtipule; both they and the branches terminated by diſtant umbels of leaves and flowers. Leaves ſeveral, at remote diſtances in whorls. Petiole jointed at the baſe, round, ſlender, ſmoothiſh, ſpreading a little,

about

about two inches in length, green. Leaflets on ſhort petioles, equal, quite entire, flat, ſpreading very much, about half an inch in length, above green and ſmooth, underneath dotted, more or leſs purple-fleſh-coloured, appearing denſely villoſe in the magnifier, with a row of orange dots, becoming black in the dried leaves, and obſervable only in the microſcope with the light thrown on it. Peduncles jointed at the baſe, axillary, round, pubeſcent in the magnifier, green, the length of the leaves; with bractes towards the top oppoſite, erect and jointed: above theſe they are nodding and purple. Calyx villoſe: leaflets oblong, blunt with a little point, erect with ſpreading tips, green, gibbous on the back below the tip with three or four calluſes, which are oblong and yellow. Corolla bell-ſhaped, three times as long as the calyx, ſmooth: claws yellow, almoſt upright, a little longer than the calyx: borders wide, rounded, ſpreading very much and reflex, whitiſh with a ſlight bluſh of purple. Filaments connate at the baſe: interior equal, hirſute with ſimple and capitate hairs; the toothlets alſo hirſute: exterior ſmooth. Anthers oblong, incumbent, yellow. Germ oblong, five-grooved, pale green, ſmoothiſh. Styles hirſute with ſimple and capitate hairs. Stigmas papilloſely muricated, not pencilled [b].

Cultivated in 1739, by Mr. Miller [c].

89. Stipe filiform, ſmooth, ſtriated, leafleſs, looſe, a foot high and more, together with the branches terminated by a denſe umbel of leaves and flowers. Branches alternate, directed one way, ſtriated, upright. Leaves ſeveral, ſmooth. Petiole jointed at the baſe, ſtriated, about an inch long. Leaflets ſubſeſſile, green, having glandular dots thinly ſcattered over the edges. Scapes ſeveral, jointed at the baſe, hairy, longer than the leaves, with oppoſite, jointed, briſtle-ſhaped bractes, tawny at the tip, a little above the middle. Calycine leaflets oblong, blunt with a point, rough-haired, ſomewhat ſtriated, glandular, tawny at the tip. Corolla three times as long as the calyx, yellow at the baſe, in other parts violet. Filaments united at the baſe into one hirſute body: interior very ſhort toothletted, equal, hirſute with ſimple hairs: the toothlets alſo hirſute: exterior ſmooth. Germ hirſute. Styles hirſute with ſimple hairs [d].

Theſe are all natives of the Cape of Good Hope.

90. Stipe ſcaly, leafleſs, ſimple, terminating in a leafy flowering umbel. Leaves ſeveral, petioled. Leaflets ſeſſile, cloven beyond the middle, cleſts lanceolate. Scape ſingle, with two bractes about the middle. Flower long.—Native of Virginia [e].

91. Root perennial, branched, round, knobbed, creeping, with very fine fibrils on every ſide, partly white, partly red, having an ovate acute thick rigid ſcale like a tooth at the knobs. Stipe partly ſubterraneous, partly ſtanding out, ſometimes very little, ſometimes ſeveral inches, then procumbent and ſtriking roots into the ground, toothletted at the knobs like the root, round, ſomewhat hirſute, red, cloſely toothletted above with the permanent joints of decayed leaves, perennial, putting forth from its top ſeveral aggregate leaves and ſcapes. Petiole jointed, round, ſomewhat hirſute, red eſpecially at bottom, from two to three inches long, almoſt upright but weak. Leaflets ſubſeſſile, near half an inch long, wider, green and hirſute on both ſides, ſhortly ciliate. Scapes one or two, jointed at the baſe, round, ſomewhat villoſe, red, the length of the leaves; with embracing, villoſe, jointed bractes above the middle. Calycine leaflets oblong, acute, ſometimes bifid, ſomewhat hirſute, ciliate, purple at the tip, upright. Corolla three times as long as the calyx, white, beautifully veined with purple, bell-ſhaped: claws upright: borders obovate, rounded, ſpreading very much. Filaments very ſlightly connate at the baſe, ſmooth: interior toothleſs, equal. Anthers oblong, incumbent, pale yellow or whitiſh. Germ ovate, ſmooth. Styles ſmooth. Capſule blunt, ſmooth [f], ovate-oblong, membranaceous, diaphanous, five-cornered, five-lobed, five-celled, ten-valved, opening longitudinally at the external angles. Receptacle none, except two papillæ, ſurrounded by a yellow ring, in the central angle of the cells, to each of which one ſeed is faſtened. Seeds regularly two, ſcarcely ever more, ovate, compreſſed like a lens, with rugged, raiſed ſtreaks, ruſſet-yellow: a fleſhy white aril inveſts the whole ſeed, at firſt ſmooth and cloſed on every ſide, but at length opening elaſtically at the tip and rolling back, it wrinkles up and throws off the ſeed with conſiderable force [g].

Mr. Curtis remarks, that the leaflets are of a yellowiſh green colour, frequently purple underneath; that the petiole proceeds from a little bulb, which forms a kind of ſheath to it, and that although round at bottom, the upper part is grooved on one ſide; that the calycine ſegments are bluntiſh and membranous at the edges; that the petals adhere together from the baſe juſt above the claws, which bend a little inward, that they are ſlightly crenated and tinged at bottom with yellow; that the anthers are bilocular; that the germ is four-cornered, the ſtyles very ſlender and a little longer than the ſtamens, and the ſtigmas blunt; that there are three heart-ſhaped ſeeds in each cell, grooved longitudinally, of a bright reddiſh brown colour; that like the Violet it continues producing ſeed-veſſels and ſeeds during the greateſt part of the ſummer, without any appearance of expanded bloſſoms, which are only obſervable in april and may; and that as it has done flowering, the flower-ſtalk, as in many other plants, bends down, and when the ſeed is ripe, again becomes upright.

Linneus remarks, that the leaflets in wet weather are erected, but hang down in dry weather. They are alſo ſaid by ſome authors to manifeſt a degree of ſenſibility on being ſtruck.

Villars obſerves, that this elegant little plant has the leaves of Trefoil, the taſte of Sorrel, and the flower of Geranium: from which laſt genus this is diſtinct, according to Juſſieu, in the number of ſtyles, the form of the capſule and manner of its opening, its ſtraight corcle or heart, without any periſperm or albumen.

Wood-Sorrel is common in Europe in woods, and occurs alſo among buſhes, in hedges and on heaths. It is alſo found in Japan. It is called, ſays Gerarde, Wood Sour, Sour Trefoil, Stubwort, and Sorell du Bois; by herbariſts Alleluya and Cuckow's meat, "by reaſon when it ſpringeth forth and flowereth, "the Cuckow ſingeth moſt, at which time alſo Alle-"luya was wont to be ſung in churches." The names Alleluya and Lujula however are corrupted from the Calabrian name *Juliola*. It is called *Stubwort*, I preſume, from its covering the ground among the ſtubs in coppices, when they are cut down. In French it is *la petite Oſeille* or *Surelle*, and *Pain à Coucou*.

A variety is found with purple flowers. It is ſaid to be a leſs plant and to flower later. In a hollow lane between Owram and Hallifax.

Wood Sorrel has a grateful acid taſte, more agreeable than common Sorrel, and therefore proper to be uſed in ſalads: its acid approaches nearly to that of the juice of lemons, or the acid of tartar, with which it alſo correſponds in its medical effects, being eſteemed refrigerant, antiſcorbutic and diuretic. An infuſion of the leaves, or a whey made by boiling the plant in milk, is uſeful in ardent fevers, to allay inordinate heat, and to quench thirſt [h]. The London College directs a conſerve of the leaves and petals to be made by beating them with thrice their weight of fine ſugar, and orange peel. It is called *Conſerva Lujulæ*. The expreſſed juice depurated, properly evaporated, and ſet in a cool place, affords a chryſtalline acid ſalt in conſiderable quantity, which may be uſed wherever vegetable acids are wanted. It is employed to take iron moulds and ink-ſtains out of linen, and is ſold under the name of eſſential ſalt of Lemons [i]. This ſalt, when genuine, which it ſeldom is, conſiſts of the vegetable alkali and a peculiar acid, which according to Bergman ſeems more allied to the acid of ſugar than

[b] Jacquin. [c] Hort. kew. [d] Jacqu. from Thunberg. [e] Jacqu. from Linn. [f] Jacquin. [g] Gærtner. [h] Woodville. [i] Withering.

than that of tartar. What is ſold for it in this country appears ſometimes to conſiſt of C. Tart. with the addition of a ſmall quantity of vitriolic acid [a]. For taking out ſpots in linen, the ſtained part is dipped in water, ſprinkled with a little of the ſalt powdered, then rubbed on a pewter plate, after which the ſpot is waſhed out with warm water [b].

Dr. Beddoes informs us that the leaves and ſtalks wrapped up in a cabbage leaf, and macerated in warm aſhes until reduced to a pulp, have been ſucceſsfully applied to ſcrophulous ulcers. This poultice ſhould remain on the ſore for twenty-four hours, and be repeated four times. Afterwards the ulcer is to be dreſſed with a poultice made of the roots of the Meadow-ſweet (Spiræa Ulmaria) bruiſed and mixed up with the ſcum of ſour butter-milk [c].

Doubtleſs ſome of the foreign ſpecies may be ſuperior to this in the ſame way. Thunberg ſays that Oxalis cernua grows to the greateſt ſize and in the greateſt abundance of any ſpecies at the Cape of Good Hope, and that a good ſalt was prepared from it [d]. But he does not inform us in what quantity. Twenty pounds of our Wood Sorrel leaves freſh yield ſix pounds of juice, from which two ounces, two drams and one ſcruple of ſalt have been obtained [e].

92. Bulb ovate, acute, often looſe, covered with a browniſh ſkin. Stipe ſubterraneous, two inches or more in length, terminated by an umbel of leaves and flowers. Leaves ſeveral, quite ſmooth, digitated, ſpreading out wide in a ring. Petiole jointed at the baſe, the joint wide, channelled and embracing, compreſſed a little, thick. Leaflets about eight, oblong or lanceolate-oblong, bluntiſh, glaucous-green above, frequently dark purple underneath, dotted on both ſides, about an inch long. Scapes few, jointed at the baſe, upright, compreſſed a little, thick, ſmooth, almoſt the ſame length with the leaves: bractes approximately alternate at top. Calycine leaflets ovate, ſharpiſh, upright, green. Corolla ſeveral times as long as the calyx, all yellow. Claws upright. Borders very wide, rounded, ſpreading very much, ſmooth, with one ſide of the back red. Filaments connate at the baſe: interior toothletted, equal, hirſute with ſhort capitate hairs thinly ſet; toothlets ſmooth: exterior alſo hirſute. Anthers oblong, incumbent, yellow. Germ half-ovate, ſmooth, pale green. Styles ſmooth [f].

93. Bulb roundiſh, the ſize of a hazel nut, covered with a brown ſkin. Stipe ſtanding out, ſcaly, ſmooth, the ſize of a pigeon's quill, thickened above, purple, leafleſs, almoſt upright, but through weakneſs frequently proſtrate, from half an inch to three inches in length, terminating in an umbel of leaves and flowers. Leaves about five digitate, ſmooth. Petiole narrowly and ſhortly jointed at the baſe, compreſſed a little, thick, firm, green or red, one or two inches long. Leaflets from five to nine, ſeſſile, lanceolate-linear, blunt, quite entire, ſometimes recurved at the tip, very minutely dotted on both ſides, but much more apparently underneath, green, almoſt upright, from one to two inches in length. Scapes ſeveral, narrowly and ſhortly jointed at the baſe, almoſt half round, ſmooth, almoſt upright, of the ſame length and thickneſs with the petioles: bractes alternate, near the top. Calycine leaflets lanceolate, acute, erect with the tips ſpreading, pale green, with dirty purple dots ſcattered over them above, ciliate on the edges with capitate hairs, in other parts ſmooth. Corolla three times as long as the calyx, ſubcampanulate, the whole yellow, except the back of the borders, which is purple: borders obovate, rounded, quite entire, wide. Filaments united at the baſe: interior toothletted, equal, having very ſhort capitate hairs thinly ſcattered over them, with ſmooth toothlets: exterior hirſute with capitate hairs. Anthers oblong, incumbent, yellow. Germ ovate-oblong, five-grooved, ſmooth, pale. Styles ſomewhat hirſute with capitate hairs underneath, in other parts ſmooth [g].—Introduced in 1775, by Mr. Francis Maſſon [h].

94. Bulb ovate-roundiſh, covered with a brown ſkin, the ſize of a hazel nut, commonly looſe. Stipe ſubterraneous, ſtanding out above and furniſhed there with large imbricate ſcales, about an inch in length, the thickneſs of a reed, ſmooth, round, terminated by an umbel of leaves and flowers. Leaves ſeveral, ſmooth, digitate. Petiole jointed at the baſe, roundiſh, thick, green, almoſt upright, weak, three or four inches long. Leaflets from ſix to nine, blunt, dotted, almoſt upright, three inches long, and three or four lines wide. Scapes ſeveral, having a long joint at the baſe, almoſt upright, weak and therefore often reclining, roundiſh, the ſame thickneſs with the petioles, ſmooth, pale green: with bractes approximately alternate above. Calycine leaflets four, lanceolate, erect with a bluntiſh reflex tip, ſmooth, pale green; a fifth double the ſize of the others, ſpatulate, rounded, and the whole erect. Corolla three times as long as the calyx, dark yellow within, ſulphur-coloured without, bell-ſhaped, wide, ſpreading very much above. Filamens connate at the baſe: interior toothletted, equal, very hirſute with capitate hairs; the toothlets ſmooth: exterior hirſute in like manner. Anthers incumbent, yellow. Germ oblong, ſmooth, pale green. Styles hirſute like the filaments [i].

95. Bulb ovate, leſs than a hazel nut, covered with a brown ſkin, looſe, putting forth a long thick fibre from its baſe. Stipe partly under, partly above ground, about an inch and half in length, ſcaly at top, almoſt upright, round, thicker than a pigeon's quill, ſmooth, purple, terminated by an umbel of leaves and flowers. Leaves ſeveral, almoſt upright. Petiole jointed at the baſe, round, dirty purple, almoſt as thick as a pigeon's quill. Leaflets ſeven or eight, oblong-linear, blunt, quite entire, green on both ſides except the midrib at the back and the baſe of the upper ſurface, which are dirty purple, three or four inches long, three or four lines wide. Scapes ſeveral, jointed at the baſe, round, ſmooth, almoſt upright, nearly the ſame length with the leaves: bractes approximately alternate above. Calycine leaflets lanceolate, blunt, ſmooth, light purple, upright, equal; ſometimes but very ſeldom one of them larger and ſpatulate. Corolla five times as long as the calyx, ſmooth, yellow: claws upright, almoſt twice as long as the calyx: borders rounded, wide, ſpreading very much, with one ſide of the back more or leſs red. Filaments connate at the baſe: interior toothletted, equal, hirſute with capitate hairs, except the toothlets, which are ſmooth: exterior hirſute in like manner. Anthers oblong, twin, erect, yellow. Germ ovate, ſmooth, pale green. Styles hirſute with capitate hairs [k].

Jacquin having figured this ſpecies both in its cultivated and wild ſtate, the difference between them may there be ſeen.

96. Bulb oval, with a brown ſkin, leſs than a hazel nut, growing very deep in the ground. Stipe ſubterraneous, two or three inches long, terminated by an umbel of flowers and leaves. Leaves ſeveral, peltately multidigitate. Petiole from a wide baſe, not jointed, round, very hirſute, erect, pale green or dirty purple, in the wild plant about an inch, in the cultivated plant from two to four inches in length. Leaflets about twelve, ſpreading in an umbel, oblong-wedge-ſhaped, converging, emarginate, dotted on both ſides, ſmooth above, denſely hirſute underneath, ciliate with ſimple hairs in and about the edges, about half an inch in length. Scapes few, not jointed, very hirſute, ſpreading, about the ſame length with the leaves. Calycine leaflets lanceolate, acute, hirſute, ciliate, erect. Corolla ſix times as long as the calyx, bell-ſhaped, villoſe on the outſide: claws erect: borders obovate, rounded, white. Filaments united at the baſe: interior toothletted, equal; ſomewhat hirſute at top with ſimple hairs, in other parts ſmooth: exterior ſmooth. Anthers oblong, incumbent. Germ ovate, hirſute. Styles hirſute with long ſimple hairs [l]. Jacquin has figured the wild and cultivated plant in the ſame plate; the latter has never flowered in Europe.

[a] Woodville. [b] Curtis from Newm. Chem. by Lewis. [c] Fact. Airs. and Wither. arr. 430. n. [d] Travels, 1. 293. engl. edit. [e] Lewis. [f] Jacquin. [g] Idem. [h] Hort. kew. [i] Jacquin. [k] Idem. [l] Idem.

The five laſt ſpecies are natives of the Cape of Good Hope.

An attention to the general diſtinctions given above, in the enumeration of the ſpecies, and at the head of the deſcriptions, together with the following circumſtances, will much facilitate and abbreviate the diſcrimination of the ſpecies, which are ſo numerous in this genus.

In n. 1 to 5, 8 to 12 and 91 the root is branched; in n. 6. it is turbinate; in n. 7. fuſiform; in n. 21. fibrous; in n. 91. knobbed; in the reſt it is bulbous.

The ſpecies with ternate leaves being moſt numerous, it may be uſeful to obſerve, that the leaflets are obovate, lanceolate or oblong in n. 41 to 46; linear from n. 47 to 54; all wedge-ſhaped in n. 55 to 58; the middle leaflet wedge-obovate, and the lateral ones oblong in n. 59 to 66; all roundiſh and ſcarcely emarginate in n. 67 to 76; all or the middle leaflet only obcordate in 77 to 91.

The peduncle or ſcape is not jointed in n. 2. 4. 22 to 27. 30. 34. 40. 47. 78. 96; in the reſt it is jointed. Moſt of the ſpecies have two bractes on the flower-ſtem; but n. 34, 35, 36. have not any. N. 40. has only one bracte; and ſome of the cauleſcent ſpecies have an involucre of ſeveral leaflets.

The two bractes are oppoſite in n. 11. 13, 14. 17, 18, 19. 25. 31. 46. 59 to 66. 76. 78 to 81. 83, 84. 87 to 91. In the reſt they are alternate. In ſome of the ſpecies they are ſubalternate or ſuboppoſite, and cannot therefore very eaſily be diſtinguiſhed.

The ſituation of theſe bractes on the ſcape or peduncle is alſo worth remarking. In the following ſpecies they are at or near the bottom; n. 13, 14, 18, 19. 67, 68. 70, 71. 73, 74, 75. 77, 78, 79. In n. 17, 26. 38. 53. 59. 61. 66. 69. 76. 81. 86. 89. 91. above the middle. In n. 11. 63, 64. 72. 85. 90. in or near the middle. In n. 33. 42, 43. 60. 62. 65. below the middle. In n. 22 to 25. 31. 37. 39. 44 to 47. immediately below the calyx. In the reſt they are near the top, or higher than thoſe which are above the middle; but lower than thoſe which approximate to the calyx.

The prevailing colour of the Corolla is yellow: in many however it is red, violet purple, red purple or fleſh-coloured, as in n. 4. 5. 14. 17. 18. 22 to 30. 32. 33. 34. 36. 45 to 50. 54. 67, b. 69. 70. 74. 76. 82. 83. 89. In n. 15. it is blue or fleſh-coloured. In n. 51. 53. 63, b. 67. 68. 75. 88. 91. 96. it is white and red. In n. 58. white and violet. In n. 37. 39. 44. 52. 55. 56. 59. 60. 61. 62. 64. 66. 71. 72. 73. 78. 79. 81. 85. 86. 96. it is white. Theſe have frequently a tinge of yellow, red or purple. In all the reſt the corolla is yellow.

The filaments are free or ſeparate in n. 21. and in ſome, as n. 13. 35. 40. 91. they are very ſlightly united at the baſe, ſo that in n. 13. particularly they may almoſt be conſidered as diſtinct. In the other ſpecies they are monadelphous.

Some of theſe filaments are ſmooth: as n. 11. 13. 16. 19. 25. 31. 35. 40. 44. 47. 50. 57. 58. 78. 83. 90. The others have the interior filaments hairy, either with ſimple hairs, as in n. 1. 2. 14. 15. 21 to 24. 28. 30. 43. 49. 64. 77. 81. 85. 89. 96: or capitate hairs, as in n. 4. 9. 10. 26. 27. 29. 32 to 34. 36 to 39. 41. 42. 45. 46. 48. 52 to 56. 59 to 63. 65 to 76. 79. 80. 82: or both, as in n. 17. 18. 51. 88. The following only have the exterior filaments hairy; n. 15. 21 to 24. 27. 28. 30. 31. 33. 41. 45. 46. 48. 49. 51. 56. 57. 58. 67. 68. 69. 81. 82. 84. 92 to 95: in the reſt they are ſmooth.]

PROPAGATION AND CULTURE.

The European and North American ſorts require no particular culture. If the roots of the common Wood Sorrel are planted in a moiſt ſhady border, they will thrive and multiply, and if kept clean from weeds will require no other care. If the ſeeds of the other ſorts are ſown in an open border, the plants will riſe freely, and if they are permitted to ſcatter, there will be a plentiful ſupply of plants.

The numerous ſpecies from the Cape of Good Hope, muſt be planted in pots, which may be ſheltered in the dry ſtove, or under a hot-bed frame in winter, where they may have as much free air as poſſible in mild weather. Moſt of them may be eaſily increaſed by offsets from the roots, or bulbs which come out from the ſide of the ſtalks, generally in great abundance.

[Of O. reptatrix in particular Jacquin ſays that as it runs along it puts forth bulbs in ſuch abundance as in a ſhort time to fill the pots with plants; but that in four years during which he had cultivated it, he had only a ſingle flower; which is common in plants that are ſuffered to run at the roots.]

The ſorts from the Eaſt and Weſt Indies being more tender than theſe, require to be placed in a ſtove kept to a moderate degree of warmth in winter. They are propagated by ſeeds, ſown in pots, plunged into a moderate hot-bed. When the plants come up, ſet them ſingly in pots filled with light ſandy earth, and plunged into a freſh hot-bed, ſhading them from the ſun till they have taken new root; after which they muſt be treated in the ſame manner as other tender plants from the ſame countries.

[Jacquin remarks, of O. Barrelieri (n. 4.) from South America, that when ſowed early in the ſpring, it grew luxuriantly in the ſtoves, produced ſeed abundantly, which from the elaſticity of the capſule could not be collected without great difficulty, and that it always periſhed in the winter: but that when it was ſown later in the ſeaſon, it ſometimes continued through the winter, and flowered the next ſpring, but always continued in a langtind ſtate.

DESCRIPTION, *&c.*

This plant, which is a native of Peru, and is very nearly allied to *Mirabilis*, under which genus it is ranged by Cavanilles; is made a diſtinct genus by L'Heritier, on account of its having only three ſtamens, and the calyx enlarged and peltate attending the fruit. Cavanilles obſerved three and four ſtamens in the cultivated plant. See his deſcription under *Mirabilis* viſcoſa.

Claſſ. 16. 2. Monadelphia Pentandria.

Nat. order of *Tribilatæ*. Meliæ, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-toothed, acute, very ſmall.

COR. *Petals* five, with long claws converging in form of a tube: *borders* oblong, blunt, ſpreading.

STAM. *Filaments* cylindrical, ſheathing the ſtyle, five-toothed at top. *Anthers* five, oblong, erect.

PIST. *Germ* five-lobed, ſurrounded by a gland. *Style* filiform, higher than the corolla. *Stigma* capitate.

PER. five-celled.

ESSENTIAL CHARACTER.

One-ſtyled. *Cal.* five-toothed. *Pet.* five, long. *Filam.* ſheathing the ſtyle, five-toothed at top; teeth antheriferous. *Stigma* one. *Capſ.* five-celled.

SPECIES.

SPECIES.

1. Ozophyllum foetidum.
Ticorea foetida.
Aubl. guian. p. 689. *t.* 277. *Lin. Syſt. Nat. Gmel. p.* 1009. *Cavan. diſſ. p.* 362.

DESCRIPTION, *&c.*

This is a ſhrub of ten feet high or more, and often four or ſix inches in diameter. The bark is green and ſmooth: the wood white, tender, and fragile. The branches twiggy, and garniſhed with alternate leaves: each leaf is digitated, having three large lobes, and growing on a footſtalk of five or ſix inches long. The lobes of the leaves are green, ſmooth, ſoft, and oval, and terminate in a long point: the middle lobe is larger than the reſt, being ſometimes more than a foot long and four inches wide: each lobe is divided by a longitudinal nerve, which is prominent beneath. The flowers ſpring from the boſoms of the leaves, at the extremity of the twigs and branches. Their common footſtalk is more than a foot long, and divides at its ſummit into ſeveral ſmaller ones, on each of which are placed alternate, ſeſſile flowers. The calyx is green: the corolla white, each petal being about an inch long, and as it were glued or united to each other longitudinally by their borders, ſo as to form a kind of tubular figure, with the upper part ſpreading: theſe petals cover a white membranaceous tube, which on its upper part divides into five ſhort filaments ſupporting at their points the anthers.

This ſhrub is a native of the foreſts of Guiana; flowering in february. The leaves, when bruiſed, emit a diſagreeable ſmell much reſembling that of the Stramonium.

Stamens ſtanding out.

DESCRIPTION, *&c.*

1. Stem twining, filiform, ſmooth and even. Leaves oppoſite, petioled, cordate, acuminate, quite entire, nerved, ſpreading a little, paler underneath, an inch long, very ſmooth and even. When the plant is young the leaves are lanceolate, but in its more advanced ſtate they are ovate. Petioles round, grooved above, ſmooth, a little ſhorter than the leaf. Flowers axillary, in brachiate panicles, coming out ſucceſſively. Peduncle round, ſmooth, the length of the petiole. The lower pedicels oppoſite, the upper alternate. Calyx ſuperior, ſmooth; ſegments acute, erect, ſeveral times ſhorter than the corolla. Tube of the corolla inflated, white-tomentoſe on the outſide, within purple, white villoſe at top. Border five or ſix-parted, ſpreading; ſegments rounded, curled, white, a line in length; opening of the tube purple, villoſe, a little cloſed. Filaments five or ſix, faſtened longitudinally to the baſe of the corolla, capillary, red, ſhorter by half than the tube. Anthers inſerted into the back, linear, erect, ſtriated, whitiſh. Germ ſurrounded by a very ſhort wreath, obtuſely ſix-lobed, ſmooth, purple. Style erect, the length of the filaments, purple. Stigmas two, capillary, curled, whitiſh, longer than the anthers. Fruit a berry crowned with the calyx, globular, when unripe green, very ſmooth and brittle, commonly two-celled, ſometimes but rarely three-celled. Seeds two or three.

Frequently the calyx is ſeven-leaved, and the corolla ſeven-cleft; ſometimes the calyx is ſix-leaved. It is now and then found with ſeven ſtamens. In drying the plant turns black. When freſh it has a very ill ſmell. It varies with wider, ſhorter leaves; and with narrower, longer leaves [a].

Retzius informs us, that beſides the ſpecimen which he had from Linneus, with a twining ſtem, and cordate acuminate leaves, tomentoſe underneath: he had another from Bladh, with the branches ſtiff and ſtraight, the leaves ſmooth, oblong, linear-lanceolate, blunt, and the panicle more denſe. He does not determine whether they are diſtinct ſpecies or varieties only. Both have the flowers racemed, in a dichotomous or trichotomous panicle.—Native of the Eaſt Indies and Japan.

2. This differs from the preceding chiefly in having wider ovate acuminate leaves, many-flowered cymes, and the ſegments of the corolla narrower and ſharper, beſides the diſtinction pointed out in the ſpecific character.—Native of the iſland of Mauritius [b].

PÆDEROTA.
Lin. gen. n. 26. *Reich. n.* 27. *Schreb. n.* 33. *Juſſ.* 120. Bonarota. *Mich.* 15.

Leaves roundish-ovate, helmet of the corollas entire.

3. Pæderota? minima.
Lin. spec. Willd. 77. *Retz. obs.* 5. 10.
Leaves oblong entire opposite, flowers axillary opposite, teeth of the calyxes hirsute within.

DESCRIPTIONS, *&c.*

1. This differs from the second in having simple stems, the lower leaves alternate, dryer, more wrinkled and not at all shining, the helmet bifid and entire, ascending. [c].—Native of Italy and Carniola. It has the trivial name, from Agerius, who first found it near Vicenza.

2. Root branched, fibrous, perennial. Stems round, simple, villose, erect. Leaves opposite, dry, acutely serrate. Raceme terminating, oblong. Bracte longer than the calyx, linear, placed close to the corolla. Corolla yellow, four lines in length, with the lip equally trifid. Style five lines long, slightly dilated at top and truncated, incumbent on the lower lip. The cells of the capsule separate in such a manner, that they might be taken for two capsules, if it were not for the single receptacle. Seeds rufous, twenty-five at most in a cell [d].

Micheli's n. 2. f. 2. with a rounder leaf, is a variety of this. Scopoli has given eight varieties.—These are natives of the mountains of Austria, Carniola and Italy. Micheli named these plants *Bonarota*, from Filippo Bonarota, Senator of Florence, fellow of the Botanic Academy there, &c.

3. This has the appearance of Elatine Hydropiper. Stems an inch and half high, seldom branched, rooting at the base. Leaves blunt, quite entire, naked. Flowers sessile, solitary. Calyx five-cornered, bell-shaped, with the teeth hirsute within. Native of the East Indies, where it was found by Koenig, on whose authority it is placed in this genus [e].

Pæderota racemosa of Houttuyn is Hemimeris montana, *Lin. suppl.*]

DESCRIPTIONS, *&c.*

1. Root brown, composed of a few cylindrical or fusiform tubers, a span in length, united at top; the flesh white with little taste. Stem, from a radical leafless sheath, two feet high, the thickness of a reed, slender, round, with scarcely conspicuous grooves descending from each petiole down both sides, green tinged with red, naked at bottom. Leaves alternate on long round petioles, channelled above. Leaflets three-parted; segments ovate-lanceolate, the middle one simple, the middle of the lateral ones three-parted

[a] Scop. ann. [b] Scop. carn. [c] Retzius. [d] Willdenow.

or two-parted, the outer ones (only in the loweſt leaves) bifid. The higheſt leaf except one has the lateral leaflets ſimple, and the middle one three-parted; the upper or floral leaf is ſimply three-parted. The whole plant is very ſmooth, and ſhining. The ſtem in the Daurian plant is often three-flowered, with the axils of the upper leaves putting forth long faſtigiate peduncles. The calyx is raiſed above the floral leaf on a very ſhort thick peduncle, and is four-leaved; the two outer leaflets narrow, green, acuminate; the two inner broad-concave, ſubacuminate, pale red. Petals eight, very large, milk white, oval, concave. Stamens about one hundred and fifty, with the filaments as well as anthers yellow. Anthers oblong, erect, four-grooved. Within the ſtamens is a fungoſe, ſubcontinuous, lobed crown, more ſlender than in its congeners. The germs are quite ſmooth, ſhining, conical, purple at the tip. The ſtigma is compreſſed into a comb or creſt, and is ſuborbicularly hooked. Seeds when ripe of a yellowiſh teſtaceous colour, and oval-globular.

It differs from the common Peony (P. officinalis) remarkably: 1. in having the ſtem more ſlender, rounder, ſcarcely grooved, more rigid; whereas in P. officinalis it is toroſely ſix or ſeven-grooved; 2. in having the leaves larger, biternate, with broader ſmoother leaflets, ſhining very much on both ſurfaces, undivided, with the veins ſcarcely prominent underneath; whereas in that the leaves are ſubtriquinate or triternate, with the primary leaflets bifid, the lateral ones frequently accompanied by a ſmaller acceſſory leaflet; 3. in having the floral leaf more remote; 4. in the colour of the flower, and eſpecially the pleaſant ſmell like that of Narciſſus; 5. in the ſmoothneſs of the germs; and 6. in having the root and herb more inſipid. It alſo flowers later.

Native of Siberia. Well known among the Daurians and Mongols on account of the root, which they boil in their broth, and the ſeeds, which they grind and put into their tea: they call the plant *Dſchina*; in Ruſſian it is *Marjin koren bjelyi*[1].]

2. α. The roots of the Common or Female Peony are compoſed of ſeveral roundiſh thick knobs or tubers, which hang below each other, faſtened with ſtrings; the ſtalks are green, about two feet and a half high; the leaves are compoſed of ſeveral unequal lobes, which are variouſly cut into many ſegments; they are of a paler green than thoſe of the Male Peony, and are hairy on their under ſide; the flowers are ſmaller, and of a deeper purple colour.

[According to Haller, the root is glandular: the leaves firm, ſhining, pinnate, with the pinnas pinnate in two pairs with an odd one at the end; the pinnules ovate-lanceolate, alſo half-lobed and half three-lobed confluent with the middle nerve. Stem a foot high, branched.

According to Scopoli, the leaves are decompound; the leaflets lanceolate, acuminate, ſeſſile, decurrent, acuminate, lobed and ſimple. The firſt leaves put forth three petioles, one of which bears one leaf, and the others two; all ovate and blunt. Under the calyx a leaf or two. Petals ſix or ſeven. Filament purple. Anthers yellow. Stigmas are brown claws with a yellow margin.]

β. The roots of the common Male Peony are compoſed of ſeveral oblong knobs hanging by ſtrings faſtened to the main head. Stems the ſame height with the preceding. Leaves compoſed of ſeveral ovate lobes, ſome of which are cut into two or three ſegments; they are of a lucid green on their upper ſide, but are hoary on their under. The ſtems are terminated by large ſingle flowers, compoſed of five or ſix large roundiſh red petals. Germs two, three, and ſometimes five, joining at the baſe, and covered with a whitiſh hairy down; theſe afterwards ſpread aſunder, and open longitudinally, expoſing the roundiſh ſeeds, which are firſt red, then purple, and when ripe perfectly black. The flowers of both appear in may, and the ſeeds ripen in the autumn.

[Haller remarks, that this differs from the preceding in having the leaves leſs diſform, and the root deſtitute of glands. It is ſcarcely neceſſary to obſerve that the old names of Male and Female have nothing to do here with the ſexes, the flowers of both being hermaphrodite.

Native of ſeveral parts of Europe, as Switzerland, Dauphiné, Carniola, Piedmont, Silefia; alſo of mount Ida, China and Japan. It was cultivated here in 1562, according to Turner[2].]

Several varieties of the Female Peony with double flowers, differing in ſize and colour, are cultivated in the Engliſh gardens. The Male Peony alſo varies with pale, and white flowers, and with larger lobes to the leaves.

[Theſe plants alſo vary much in different countries. Pallas informs us that the native plant of Mount Caucaſus differs conſiderably from that which is cultivated in gardens. Loureiro mentions ſome varieties in China, and ſays that there are many others. Of the numerous varieties to be found in old authors I ſhall ſet down only thoſe which Mr. Miller has given as ſpecies.]

γ. Foreign Peony with a deep-red flower. The roots are compoſed of roundiſh knobs, like thoſe of the Female Peony. The leaves alſo are the ſame, but of a thicker ſubſtance. The ſtalks do not riſe ſo high. The flowers have a greater number of petals, and appear a little later.—It is a native of the Levant. The large double purple Peony is probably a variety of this.

[Parkinſon calls this the ſingle red Peony of Conſtantinople, and ſays that the flower has eight leaves, of a deeper red colour than either the ſingle or double Peonies, and not purpliſh at all, but rather of the colour of an ordinary red Tulipa. The roots have longer clogs, and not ſo ſhort as the ordinary female kind, and of a paler colour on the outſide.

Johnſon, in his edition of Gerarde's herbal calls it Turkiſh Peionie, and ſays that the ſeed was ſent to Cluſius from Conſtantinople. Cluſius informs us, that the corolla has eight, ten or more petals, and that he raiſed plants of it in 1588.]

δ. Hairy Peony, or Female Peony with a larger double red flower, has alſo roots like the common female Peony: but the ſtalks are taller, and of a purpliſh colour; the leaves are much longer, with ſpear-ſhaped entire lobes; the flowers are large, and of a deep-red colour.

ε. Roots compoſed of oblong fleſhy tubers of a pale colour. Stalks about two feet high, pale green. Leaves compoſed of ſeveral lobes, irregular in ſhape and ſize, ſome having ſix, others eight or ten ſpear-ſhaped lobes, ſome cut into two or three ſegments, and others entire; they are of a pale green, and downy on their under ſide. The ſtalks are terminated by one flower of a bright-red colour, a little leſs than that of the common female Peony, and having fewer petals. Germs two or three, ſhorter and whiter than in that. It alſo flowers ſomewhat later. The ſeeds were brought from the Levant, and plants were raiſed from them both with ſingle and double flowers.

Mr. Miller, in his figures, adds, that ſome of the leaves are compoſed of eleven, and others of thirteen lobes; that the two ſide diviſions next the ſtalk are for the moſt part compoſed of three lobes, but the middle one, which is extended in length, is commonly compoſed of ſeven lobes; the lobes narrow, ſmooth and entire, ſmaller than thoſe of the common ſort, and covered with a ſoft down; that the ſtalks are ſeldom more than a foot and half in height: that the germs are generally three, ſometimes four or five; and that the capſules are oblong, two or three larger than the others.

ζ. Peony of Portugal with a ſingle ſweet flower has not roots compoſed of roundiſh tubers, but has two or three long taper forked fangs like fingers. The ſtalk riſes little more than a foot high. The leaves are compoſed of three or four oval lobes, of a pale colour on their upper ſide, and hoary underneath. The ſtalk is terminated by a ſingle flower, which is of

[1] Pallas.

[2] Hort. kew.

a bright

a bright red colour, ſmaller than the preceding, and of an agreeable ſweet ſcent. The ſeeds were ſent to the Chelſea garden by the elder Juſſieu, who brought them from Portugal, where this plant grows naturally.

[3. Root tuberous, diſſorm, very large, deſcending by cylindrical proceſſes a ſpan in length, yelloviſh without, white within, both freſh and dry having a very ſtrong ſmell and taſte of bitter almonds or peach kernels. Root-leaves none, but red, awnleſs ſheaths, whence the ſtems; which are ſeveral, from eighteen to twenty-ſeven inches in height, the thickneſs of the little finger, round, very ſmooth, alternately and frequently leafy above, without any ſtipules at the petioles. Leaves on a flat petiole channelled above, almoſt ternate, but with the partial petioles ſo margined with the leaf running along them, that they may be called tripartite. Leaflets ſoft, bright green, paler underneath, ſhining, very ſmooth; the middle one deeply three-parted, and the middle part of theſe ſix times, the lateral ones four times deeply gaſhed: the ſide leaflets two-parted, one part ſix times, the outer five times gaſhed and ſlightly two-parted. All the ſegments of the leaflets long and ſharp. The upper leaves towards the flower are gradually larger and leſs gaſhed; the laſt are three-cleft, with the middle ſegment five-cleft. At the calyx itſelf are two linear leaflets, bifid or trifid at the tip. Flower nodding a little: the calyx has three lanceolate leaflets, equal to the corolla in length, purple at the baſe, leafy and reflex at the end; and three inner leaflets ovate-acuminate and concave. Corolla handſome, ſpreading a little, deep roſe-coloured, with a ſlightly viroſe ſmell, ſix-petalled, in gardens frequently ſeven-petalled: petals oblong-oval, waved, tender, the outer larger, the inner narrower. Stamens about two hundred and fifty: filaments briſtle-ſhaped, weak, twice as long as the anthers; which are large, erect, oblong, curved a little, longitudinally four-grooved, abounding very much in a pale yellow pollen. Germs three or four, very frequently five, conical, ſmooth, green, with a ſeſſile creſcent-ſhaped reflex purple ſtigma. The germ has a crown of about fifteen fungoſe, white, contiguous, ſubdidymous glands. Capſules five, coriaceous, ſmooth, ovate-acute, diſpoſed in a ſtar, in cultivation having frequently one or two aceſſary ones upright in the middle) when ripe opening at top, and exhibiting ſeveral oval-globular ſeeds, firſt red and then teſtaceous-black, which commonly do not germinate till they are a year old.

Native of all Siberia in mountainous woods. In the gardens at Peterſburgh it flowers ſooner than the other ſpecies, namely about the end of may. The root dried is uſed by the Mongols and ſome Tartars as ſauce for their meat: and Boetcher, an army ſurgeon, found it to be uſeful in intermittent fevers.

4. This has nearly the ſtature of the laſt, and is much taller than the next. Stem the thickneſs of a finger, obſcurely channelled (which it is not in P. laciniata), more rigid, naked at bottom, as that is, hence up to the flower leafy, rather more copiouſly than in the preceding. Petioles above concave-channelled, thicker and ſtiffer than in P. laciniata, trifid. Leaves trichotomous-multifid, linear, the middle trifid, divided into 14—24—14; the lateral ones into 14—22—9, or thereabouts. The uppermoſt leaves ſmaller, divided into about eighteen cleſts. The floral ones five-cleft and ten-cleft. Calyx ſeſſile: the three outer leaflets ovate at the baſe, with a leafy linear point, longer than the corolla; the three inner large, oval-conchoid, rounded, with a ſmall, briſtle-ſhaped point: green with the edge and middle purple. Petals ſeven, large, wide, leſs oblong than in P. laciniata, but of a deeper red colour, between that and P. tenuifolia, more coriaceous than in that and of a more globular figure. Stamens thirty to forty or more, with ſmaller anthers, commonly ſhrivelling and deſtitute of pollen. Germs three, conical-convex, pubeſcent, with creſcent-ſhaped very red ſtigmas. Petals ſometimes bifid. The white fungoſe glands of the receptacle round the germs are about ſeventeen, and leſs contiguous than in P. laciniata: the taſte is a little more viroſe than in that.

This plant is ſuppoſed to have originated in the botanic garden at Peterſburgh, from the ſeeds of P. tenuifolia ſown in the ſame bed with P. laciniata; and it is conjectured to be a mule between them, ſince it has not ever produced ripe ſeeds. It occurs of a much ſmaller ſize in ſome parts of Siberia.

5. Root creeping, putting forth tuberous fibres, with tubercles the ſize of a hazel nut, white, fleſhy, of a bitteriſh taſte. Stem ſcarcely a foot high, and commonly ſingle, but in the garden eighteen inches high, and ſeveral from the ſame root, but fewer than in P. laciniata. Root-leaves none. Stem round, very obſcurely grooved, ſmooth as is the whole plant, naked at bottom, having there only a few ſheathing ſcales. Leaves frequent, alternate, the upper ones gradually leſs, on a round petiole, channelled above, quinate: leaflets cut into very many narrow ſegments. The upper leaves ſimply multifid. Flower ſeſſile at the uppermoſt leaf, ſubglobular, accompanied by two leaflets, one multifid, the other ſimple, both dilated at the baſe. Calyx five-leaved; leaflets concave-gibbous, two of them exterior and acuminate. Petals eight, ſpreading, oval, very deep red. Stamens about one hundred and twenty, with pale filaments, and erect, oblong, deep yellow anthers. Germs two or three, conical, villoſe, with a creſted, reflex, vertically flat, roſe-coloured ſtigma. Capſules, in the wild plant, commonly two, in the gardens three, ovate-oblong, tomentoſe, red, when they open reflex and ſpreading, coriaceous. Seeds oblong, firſt yellow, then brown, about ſix in number, faſtened to the opening future [1].

According to Gærtner, the capſules are leguminoſe, from two to five, ovate, ventricoſe, beaked, from ſpreading reflex, pubeſcent, one-celled, opening by the upper or inner ſide. Seeds ſeveral, oblong-ſpheroidal, ſmooth, ſhining, very dark ferruginous, with a prominent, obliquely truncate, compreſſed navel at bottom, and a filiform hilum or ſcar on one ſide: they are faſtened alternately in a double row to each margin of the opening future. The number three is moſt frequent in the capſules, but in the garden it often mounts to five. But Pallas remarks, that two is the moſt common number in the wild plant.

Native of Ucraine. Introduced in 1765, by Mr. William Malcolm [2].]

PROPAGATION AND CULTURE.

The Male Peony is chiefly propagated for the roots, which are uſed in medicine; for the flowers being ſingle, do not afford near ſo much pleaſure as thoſe with double flowers, nor will they abide near ſo long in beauty.

All the ſorts with double flowers are preſerved in gardens for the beauty of their flowers, which, when intermixed with other large growing plants in the borders of large gardens, will add to the variety; and the flowers are very ornamental in baſons or flower-pots, when placed in rooms.

They are all extremely hardy, and will grow in almoſt any ſoil or ſituation, which renders them more valuable; for they will thrive under the ſhade of trees, and in ſuch places they will continue much longer in beauty.

They are propagated by parting their roots, which multiply very faſt. The beſt ſeaſon for tranſplanting them is towards the end of auguſt, or the beginning of ſeptember; for if they are removed after their roots have ſhot out new fibres, they ſeldom flower ſtrong the ſucceeding ſummer.

In parting theſe roots, always obſerve to preſerve a bud upon the crown of each offset, otherwiſe they will come to nothing; nor ſhould you divide the roots too ſmall (eſpecially if you have regard to their blowing the following year) for when their offsets are weak, they many times do not flower the ſucceeding ſummer, or at leaſt produce but one flower upon each root: but where you would multiply them in quantities, you may divide them as ſmall as you pleaſe, provided there be a bud to each offset, but then they ſhould be planted in a *nurſery-bed* for a ſeaſon or two

[1] Pallas. [2] Hort. Kew.

to get ſtrength, before they are placed in the flower-garden.

The ſingle ſorts may be propagated from ſeeds (which they generally produce in large quantities, where the flowers are permitted to remain) which ſhould be ſown in the autumn ſoon after they are ripe, upon a bed of light freſh earth, covering them over about half an inch thick with the ſame light earth. The ſpring following the plants will come up, when they ſhould be carefully cleared from weeds, and in very dry weather refreſhed with water, which will greatly forward their growth. In this bed they ſhould remain two years before they are tranſplanted, obſerving in autumn, when the leaves are decayed, to ſpread ſome freſh rich earth over the beds about an inch thick, and conſtantly to keep them clear from weeds.

When you tranſplant them, (which ſhould be done in ſeptember) you muſt prepare ſome beds of freſh light earth, which ſhould be dug, and well cleaned from the roots of all noxious weeds; then plant the roots therein ſix inches aſunder, and about three inches deep. In theſe beds they may remain until they flower, after which they may be tranſplanted where you deſign they ſhould grow. It is very probable there may be ſome varieties obtained from the ſeeds of theſe plants, as is common in moſt other flowers; ſo that thoſe which produce beautiful flowers, may be placed in the flower-garden, but ſuch as continue ſingle or ill-coloured, may be planted in beds to propagate for medicinal uſe.

The variety from Portugal requires a lighter ſoil and a warmer ſituation. The flowers though ſingle are very ſweet, which renders this worthy of a place in every good garden.

DESCRIPTIONS, *&c.*

1. This is an annual, with red, declinate, very branchy ſtems, ſcarce a palm long; leaves ſublobate, ſmooth, alternate, with footſtalks almoſt their own length: ſtipules ſmall blackiſh, lanceolate, and hiſpid. Flowers on long ſingle peduncles, which are red, and ſhorter than the leaves. Corolla roſe-coloured.

It is a native of ſandy places at Lima in Peru, where it was firſt obſerved by Dombey: it flowers in that region in july, auguſt, and ſeptember.

2. This, which is the Sida moſchata of Dombey, is alſo an annual; growing in ſandy places in the neighbourhood of Lima, where it was alſo firſt obſerved by Dombey. The whole plant is downy, and has a muſky ſmell. The ſtem is upright, branchy, and two feet high: leaves ſomewhat wrinkled, cordate-ovate, ſublobate, or obtuſely and widely crenated; they ſtand alternate. Stipules ſmall, lanceolate, and blackiſh. Flowers ſolitary, axillary, and pedunculated: peduncles jointed, and longer than the leaves. Flowers large and of a yellowiſh purple.

ESSENTIAL CHARACTER.

Receptacle chaffy. *Down* none. *Seeds* vertical, flat, margin-ciliated. *Calyx* imbricate.

SPECIES.

1. Pallaſia halimifolia.
Hort. kewenſ. 3. *p.* 498.
Coreopſis limenſis. *Jacqu. ic. vol.* 3.

DESCRIPTION, *&c.*

This is a ſhrubby plant of about two feet high; the ſtem is round, downy, of the thickneſs of a quill or more, and branchy. The leaves are alternate, footſtalked, obtuſe or a little acute, widely ovate, ſubtrinervate, very entire or elſe obſcurely denticulated, downy on both ſides, and whitiſh: footſtalks terminal, elongated, upright, round, villoſe and ſubdivided. The ray of the corolla is of a deep yellow. The corollules of the diſk yellow. The anthers red. The ſtigmas yellow. The exterior chaffs are greeniſh; the interior which are harſh, are whitiſh. The ſeeds are blackiſh with white cilias.

Profeſſor Jacquin, who has deſcribed this plant in his work entitled Ic. plant. rar. thinks it clearly to be a ſpecies of Coreopſis.

It is a native of Lima in Peru.

DESCRIPTIONS, &c.

1. Ginſeng has a fleſhy taper root as large as a man's finger, jointed, and frequently divided into two branches, [ſending off many ſhort ſlender fibres.] The ſtalk riſes near a foot and half high, and is naked at the top, where it generally divides into three ſmaller footſtalks, each ſuſtaining a leaf compoſed of five ſpear-ſhaped leaflets, ſerrate, pale green and a little hairy. [The ſtalk is erect, ſmooth, round, ſimple, tinged of a deep purple colour. The leaves ariſe with the flower-ſtem from a thick joint at the extremity of the ſtalk: they are generally three, but ſometimes more, the five leaves into which each of theſe are divided are of an irregular oval ſhape, veined, pointed, ſmooth, deep green above, on ſhort footſtalks, from a common petiole, which is long, round and almoſt erect.] The flowers grow on a ſlender peduncle juſt at the diviſion of the petioles, and are formed into a ſmall umbel at the top; they are of an herbaceous yellow colour, and appear at the beginning of june. The berries are firſt green, but afterwards turn red; and incloſe two hard ſeeds, which ripen in the beginning of auguſt [o].

[Linneus remarks, that the ſeeds produce a ternate leaf, without any ſeed-leaves, like the monocotyledonous plants. Bernard Juſſieu ſometimes obſerved three ſtyles in the flower, and three ſeeds.

Ginſeng is a native of Chineſe Tartary, from 39 to 49° of latitude, and alſo of North America. It is very abundant in Canada, in plain parts of the woods; is fond of ſhade, of a deep rich mould, and of land which is neither wet nor high. It flowers in may and june, and the berries are ripe at the end of auguſt. It is not common every where, for in ſome parts it is not to be found for ſeveral miles, but in thoſe ſpots where it grows, it is always in great abundance [p]. Mr. Cutler ſays that it grows plentifully in New England, and ſome of the neighbouring ſtates [q]: and Bartram found it in Virginia. It has never been found far north of Montreal [r]. Ginſeng has been gathered time immemorial in Chineſe Tartary. In 1709 the Emperor of China gave orders to ten thouſand Tartars to go in queſt of theſe roots, and to bring as much as they could find; every one was to give two pounds of the beſt to the Emperor, and to ſell the reſt for the ſame weight of fine ſilver. In this manner the Emperor procured twenty thouſand katye or Chineſe pounds in one years. Monſ. Sarraſin had before this, namely in 1704, tranſmitted ſpecimens of it from Canada to Paris [s]. In 1740, it was introduced here by Peter Collinſon, Eſq. [t] In 1748 a pound of Ginſeng roots was ſold at Quebec for ſix livres, but the common price was five livres. About this time the trade which the French carried on

[o] The additions are from Woodville. [p] Kalm.
[q] Mem. amer. acad. 1. [r] Kalm.
[s] Oldeck, 1. 224. engl. edit. [t] Mem. par. for 1718. p. 44.
[u] Hort. kew.

with it was very brisk. They gathered great quantities, and sent it to France, whence it was exported to China, and sold there to great advantage at the first outset, but its price afterwards fell considerably, probably by overstocking the Chinese, or because the Chinese discovered or fancied the American Ginseng to be inferior to theirs. The indians collect the roots in the woods, and sell them to the merchants, who spread them on the floor to dry, for two months or more, according to the season, turning them once or twice every day [a].

Osbeck informs us that the Chinese hang the American roots over a boiling pot, that they may sweat: and dry them afterwards. They are said to dip their own roots in a decoction of the leaves of the plant. Theirs are almost transparent, and look like horn within; the best are heavy and compact in the inside [b].

Others say that the Chinese after having washed the roots, soak them in a decoction of rice or millet-seed, and then expose them to the steam of the liquor, by which they acquire their firmness and clearness.

The Chinese name of *Yan-sam* or *Tansom*, and the American of *Garantouges* or *Garangtoging*, are both derived from the fancied resemblance which the branching root bears to the human figure. The Tartars call it *Orbeta*, the most noble or Queen of plants.

Both they and the Chinese ascribe extraordinary virtues to this root, and have long considered it as a sovereign remedy in almost all diseases to which they are liable, having no confidence in any medicine, unless in combination with it. Osbeck says, that he never looked into the apothecaries shops, but they were always selling Ginseng, that both poor people and those of the highest rank made use of it, and that they boil half an ounce in their tea or soup every morning, as a remedy for a consumption and other diseases. Jartoux relates, that the most eminent physicians in China have written volumes on the medicinal powers of this plant, asserting that it gives immediate relief in extreme fatigue, either of body or mind, that it dissolves pituitous humours and renders respiration easy, strengthens the stomach, promotes appetite, stops vomitings, removes hysterical, hypochondriacal and all nervous affections, giving a vigorous tone of body even in extreme old age. Jartoux himself was so biassed by eastern prejudice in favour of Ginseng, that he seems to give their extravagant effects full credit, and confirms them in some measure from his own experience [c]. The French in Canada use this root for curing the asthma, as a stomachic, and to promote fertility in women [d].

After all, our physicians say that we have no proofs of the efficacy of Ginseng in Europe, and that from its sensible qualities it seems to possess very little power as a medicine [e]. This is no proof, that, after all due allowances are made for popular prejudice, it may not be a good medicine in many cases, in those countries where it grows naturally.—It is commonly used in decoction; a dram of the root being long boiled in a sufficient quantity of water for one dose [f].

The dried root, as imported here, is scarcely the thickness of the little finger, about three or four inches long, frequently forked, transversely wrinkled, of a horny texture, both within and without of a yellowish white colour. To the taste it discovers a mucilaginous sweetness, approaching to that of liquorice, accompanied with some degree of bitterishness, and a slight aromatic warmth, with little or no smell. It is far sweeter and of a more grateful smell than the roots of Fennel, to which it has by some been supposed similar; and differs likewise remarkably from those roots, in the nature and pharmaceutic properties of its active principles; the sweet matter of the Ginseng being preserved entire in the watery as well as the spirituous extract, whereas that of Fennel roots is destroyed or dissipated in the inspissation of the watery tincture. The slight aromatic impregnation of the Ginseng is likewise in good measure retained in the watery extract, and perfectly in the spirituous [g].

[f] Idem. [g] Lewis, mat. med. and Woodville.

Father Loureiro doubts whether the American Ginseng be the same with the precious *Gin seng* of the Chinese. He procured seeds from Tartary, but unfortunately on being sowed they did not germinate. In the Chinese herbariums and figures the plant appears to have quinate leaves, not tern, on long scattered petioles; the leaflets broad-lanceolate and quite entire: the flowers reddish, in a terminating umbel: the fruit containing seven or eight, roundish, umbilicated seed, a little larger than a pepper-corn, brown and of a horny substance. Loureiro asserts that the efficacy of the Chinese root is very different from that of Canada, that the latter is therefore sold cheaper, and that the shape is so different that neither medical practitioners nor merchants can mistake them.—If therefore our physicians have only used the root which comes from Canada, they have not given the Ginseng a fair trial. Loureiro adds, that *Sinus Ninfa* is quite a different plant, and not esteemed.

2. This is a small tree, with round, smooth, unarmed branches. Leaves scattered, alternate, petioled, quinate, very seldom ternate, and still more seldom septenate. Common petioles round, smooth, longer than the leaves, a foot long, sheathing at the base: sheaths half embracing, within the base of the petiole above free and acuminate. Leaflets also petioled, broad-ovate, drawn to a very long point at the end, remotely notched, flat, nerved, veined, very smooth on both sides, paler underneath, somewhat rigid. Petiolets two inches long, smooth and even. Umbels terminating, five-parted, compound, on a very short common peduncle: partial peduncles very long, like racemes; somewhat verticilled or scattered, terminated by eight-rayed umbellets. The half pedicels are half an inch long and one-flowered. Universal involucre scarcely any, but small acute leaflets under the division of the pedicels and deciduous: partial involucre very minute, five-toothed. Flowers hermaphrodite all fertile. Calyx pitcher-shaped, five-toothed, teeth extremely minute. Petals ovate, acute, caducous. Filaments inserted at the edge of the calyx. Anthers ovate, twin, yellow. Germ inferior compressed. Style short, thickish, the length of the stamens, bifid at the top, seldom trifid. Stigmas simple, very short. Fruit a Berry? crowned with the calyx, roundish, compressed, smooth, two-celled or sometimes three-celled. Seeds solitary. Allied very nearly to P. arboreum.

Native of the West Indies; in Guadaloupe, and St. Christopher's [a].]

3. Stem single, not more than five inches high, dividing into three foot-stalks, each sustaining a trifoliate leaf, with the leaflets longer, narrower, and more deeply indented on their edges than in the first species. The flower-stalk rises, as in that, from the divisions of the petiole.

Native of North America. Mr. Miller had a single plant of it from Maryland, which he lost by drought before it flowered.

[It is so nearly allied to the first sort, that Linnæus doubts whether it be any thing more than a variety of that, only much smaller.

4. This is a shrub with a recurved prickle at the base and at the tip of the petioles. Leaves solitary, ternate, tern at the flowers: with ovate, blunt leaflets. Umbels peduncled, hemispherical, simple. Flowers with three styles.

Native of China [b]. Cultivated in 1773, by John Fothergill, M. D. [c]

5. Spines stout, very straight, spreading, instead of a leaf, below the abbreviated shoots of the branchlets. The shoots consist of three or four leaves without a branchlet, and among these leaves is a filiform peduncle with a simple umbel; and small white flowers. Leaves wedge-form, produced at the tip, serrate; the lower ones shorter.

Native of Japan, where it was found by Thunberg [d]. It is not mentioned in the Flora Japonica, or in his Travels.

[a] Swartz. [b] Linn. spec. [c] Hort. kew.
[d] Linn. suppl.

6. Leaves

6. Leaves petioled, digitate. Leaflets ſeven, of different ſizes, oblong, ſerrate, very ſmooth and ſhining. Umbel large, with elongated rays, not ſimple as in P. quinquefolium.—Native of New Zealand[l].

7. This is a lofty tree, with branches the thickneſs of the thumb at top; theſe, the leaves underneath, the younger petioles, the branches of the panicle, the calyxes and petals on the outſide, are all covered with a fine golden cottony down. Leaves alternate, compound. Leaflets umbelled: the younger ones from three to ſeven inches in length, the lateral ones gradually leſs, drawn to a point at each end, eſpecially on the outſide, acute, flat, firm, obſcurely veined, of a ſhining golden colour underneath, as in *Chryſophyllum Cainito*, ſmooth and even above: the full-grown ones a foot long, ovate at the baſe, nerved, obſcurely veined, ſubcoriaceous, even, glaucеſcent underneath towards the edge, with a ſomewhat unequal repand edge, very much attenuated. Petioles round; thoſe of the more advanced leaves a foot long, widening at the baſe: the partial ones three inches long: both ſmooth: thoſe of the younger leaves ſhorter. Panicle terminating, large, diffuſed: the two loweſt branches oppoſite; the reſt, as alſo the branchlets and peduncles of the umbels, alternate, round. Bractes concave: the loweſt on the branches half an inch long and trifid; the lateral ſegments ſhorter, lanceolate, the middle one awl-ſhaped and elongated: of the other branches ovate, ſmall, three-toothed: thoſe on the branchlets minute, ovate, acute, entire. Umbels pedunciled: rays commonly eight, ſometimes but ſeldom from nine to thirteen, a quarter of an inch in length, and ſpreading very much. Involucre, a ſcalelet at the baſe of each ray, minute, ovate. Flowers ſmall. Calyx only a very ſhort ſuperior rim, obſcurely five-toothed. Petals ovate, acute, a little thicker at the edge, having a longitudinal raiſed line along the middle of the upper ſurface, ſpreading a little at the tip. Nectary, a very ſhort rim, between the petals and the baſe of the ſtyles, ſomewhat fleſhy. Filaments ſcarcely any except a very ſhort proceſs from the edge of the nectary. Anthers ovate, half the length of the petals, convex at the back, curved within, terminated by a ſhort point at the tip, viſible only with a microſcope. Germ roundiſh, compreſſed a little at the baſe. Styles two, very rarely three, linear, thickiſh, erect, converging, the length of the anthers, permanent. Stigma ſharp. Berry compreſſed, roundiſh, greater in breadth than length, ſcarcely cordate at the baſe, umbilicate, crowned with the two ſtiles bent back, commonly two-celled, very ſeldom three-celled, triangular. Seed one in each cell adhering to the axis, compreſſed, nearly ſemiorbiculate, with a cartilaginous ſhell or cover.

Found by Aublet in Guiana, and Ryan in the iſland of Trinidad[k].

8. This is an upright ſhrub, ſix feet high, with a thick, juicy, unarmed ſtem, and oblique branches. Leaves bipinnate, with an odd one: leaflets laciniate-ſerrate, ſmooth: primary petioles long, ſwelling at the baſe, embracing, purple, even. Flowers red and green, terminating, in a diffuſed panicle, ending in umbels, on a long, purple, ſtriated peduncle. Calyx cup-ſhaped, with a very ſmall five-toothed border. Petals oblong, acute, thick, grooved, revolute, ſometimes ſix. Filaments five, (ſometimes ſix) placed on the calyx, ſhorter than the corolla. Anthers oblong, two-celled, incumbent, before the flower expands incloſed in the grooves of the petals. Germ ovate. Style none. Stigmas three, oblong, erect. Berry calycine, roundiſh, three-celled, with a few roundiſh ſeeds[l].—Loureiro did not find any male flower.

According to Linnæus, the leaves are bipinnate or tripinnate, with lanceolate, unequal, ſerrate-ciliate, even leaflets. Peduncle irregularly branched, or dichotomous or brachiate. Umbellets almoſt naked. Berries two-ſtyled, two-ſeeded. Seeds ſomewhat compreſſed, grooved.

Native of the iſland of Ternate. Cultivated in China and Cochinchina; where the root and leaves are uſed in medicine. The plant has a ſtrong ſmell and penetrating taſte. It is reputed to be diuretic, and to be of ſervice in the dropſy, dyſury, gonorrhœa, &c.[m]

9. Native of New Zealand[n].]

PROPAGATION AND CULTURE.

1. The Ginſeng has been introduced into the Engliſh gardens from America, and where it has been planted in a ſhady ſituation and a light ſoil, and the plants have thriven and produced flowers, and ripened their ſeeds annually, but not one of theſe ſeeds have grown. I have ſown them ſeveral years ſoon after they were ripe without any ſucceſs; I have alſo ſown the ſeeds from America ſeveral times in various ſituations, and have not raiſed a ſingle plant: and by the accounts which the miſſionaries have ſent from China, it appears that they have had no better ſucceſs with the ſeeds of this plant; ſo that I believe there is a neceſſity for the hermaphrodite plants to have ſome male plants near them, to render the ſeeds proliſic; for all thoſe plants which I have ſeen, or ſaved ſeeds from, had hermaphrodite flowers; and though the ſeeds ſeemed to ripen perfectly, yet their not growing, though I have waited three years without diſturbing the ground, confirms me in the opinion.

[This account agrees with that of Loureiro given above; and ſhows that the flowers which are apparently hermaphrodite are imperfect. It is a ſtrong confirmation of the ſexual ſyſtem, and would be a proper ſubject of experiment in the countries where this plant grows naturally. Other ſpecies ſeem to have no male flowers, but perfect hermaphrodites only, and therefore belong to the claſs Pentandria, where Swartz has placed the genus. Theſe plants are very nearly allied to the *Umbellatæ*, which have commonly imperfect flowers mixed with the perfect ones, but on the ſame plants, and in the ſame umbel.

Kalm ſays, that the American Ginſeng bears tranſplanting very well, and will ſoon thrive in its new ground: and that he was told, that the ſeeds lie one or two years in the ground before they come up.

DESCRIPTIONS, *&c.*

[This genus conſiſts of perennial plants with very large bulbous roots, from whence proceed long leaves, ſome very narrow, others broad, and a ſtrong ſtraight upright ſcape from one to three feet high, terminated by a large ſpathe, burſting on one ſide, and diſcloſing in ſome of the ſpecies many, in others only one or two white flowers of great elegance and fragrance.]

1. This has a pretty large bulbous root. Leaves long and narrow, of a grayiſh colour, and pretty thick, ſtanding upright. The ſtalk riſes among them, a foot and half high, naked, ſuſtaining one flower at the top. Nectary large, cut at the brim into many acute ſegments. Stamens long, and turning towards each other at their points, in which it differs from the other ſpecies. The flower has a very agreeable ſcent, but is of ſhort duration.

Native of Ceylon. [Cultivated by Mr. Miller in 1739.

2. Stem or ſcape a long ſpan in height, round, forked towards the top, or dividing into two pedoncles, with two oblong tender membranaceous greeniſh leaflets, and terminated each with a white flower, divided to the very baſe into ſix narrow ſegments; in the middle of theſe is a white bell-ſhaped tube, which Linnæus names the nectary, more tender than the petals, the mouth angular, and from each angle putting forth a filament, long, ſlender and white, terminated by an oblong incurved ſaffron-coloured anther. The flowers have no ſmell and ſhrivel up over the fruit. Leaves four, reclining, ſmooth, pale green and ſomewhat glaucous, rigid, ſlightly grooved in the middle, and with a ſingle ſtreak on each ſide, otherwiſe veinleſs, a long ſpan or a little more in length, an inch or an inch and half in width, produced to a point at the end. It flowers in may, from bulbs brought from Mexico [a].]

3. Leaves about a foot long and two inches broad, having three longitudinal furrows. The ſtalk riſes about a foot high, then divides like a fork into two ſmall footſtalks or rather tubes, which are narrow, green, and at firſt encompaſſed by a thin ſpathe, which withers, and opens to give way to the flowers: theſe are white and have no ſcent.

[Native of the Weſt Indies.—Dr. Browne ſays, it grows wild in moſt parts of Jamaica, and the other ſugar iſlands, with large leaves and numerous flowers, ſeldom riſing above ſixteen or eighteen inches in height.] Dr. Houſtoun brought ſome of the roots from La Vera Cruz; [and it was cultivated by Mr. Miller in 1730 [b].

Mr. Saliſbury has figured and deſcribed a ſpecies which he has often received from Barbadoes, and which he ſuſpects may be the ſame with that of Sloane and Martyn, but different from that of Commelin; which he refers to his *amœnum*, the *declinatum* of Jacquin. He names it *Pancratium fragrans*, and gives this ſpecific character.—Petioles wide; tube of the corolla ſix-cornered, not ſtreaked, ſegments longer than the tube, recurved, linear, alternately more concave, the ſinuſes of the crown repand-emarginate.—He thus deſcribes it: Plant a foot and half high. Leaves ſeven to ten, green, bifarious. Petioles ſheathing at the baſe, ſpreading, half round. The leaves themſelves much longer than the petioles, recurved, lanceolate, quite entire, blunt, a little channelled, ſmooth eſpecially above, fleſhy. Flowers very fragrant, from ſeven to twelve in a bunch. Peduncle (or ſcape) pale glaucous, among the inner leaves, a little ſhorter than they, after flowering bent down towards the ground, compreſſed, ancipital, ſmooth with a glaucous bloom, ſlightly ſtreaked, ſolid. Germ bright green, ſhortly pedicelled, oval, three-cornered, ſmooth with the ſame glaucous bloom. Tube of the corolla very pale green, two inches and an half long, hexangular with the alternate angles narrower, not ſtriated as in the other ſpecies: border ſnow-white, one-fourth longer than the tube, recurved; ſegments linear, quite entire, bluntly mucronate, the outer ones a little narrower and much more concave: crown ſnow-white, ſhorter than the border by two-thirds, funnel-form, more contracted at the baſe than the tube, repand-emarginate at the ſinuſes, but ſometimes produced into a biſid ligule, ſomewhat wrinkled, thin, even, ſhrivelling. Filaments higher than the crown by one-fourth [c].

Mr. Saliſbury affirms that Linnæus has made up his P. caribæum from the doubtful ſynonyms of Sloane and Martyn, and that of Commelin, which according to him does not belong to this ſpecies.—Miller's plant does not ſeem to be the ſame with Mr. Saliſbury's, and conſequently not Martyn's, which is undoubtedly the ſame with Miller's.]

[a] Dillenius. [b] Hort. kew. [c] Linn. tranſ. 2. 72.

4. This has a large, coated, bulbous root, of an oblong form, covered with a dark skin; the leaves are shaped like a tongue; they are more than a foot long, and one inch broad, of a deep green, six or seven of them rising together from the same root, encompassed at bottom with a sheath; between these arises the stalk, which is a foot and half long, naked, sustaining at the top six or eight white flowers, inclosed in a sheath, which withers and opens on the side, to make way for the flowers to come out. The germs are situated close to the top of the stalk, from these arise the tubes of the flowers which are three inches long; they are very narrow, swelling at the top, where the cup or nectarium is situated, on the outside of which are fastened the six segments or petals of the flower; these are narrow, and extend a great length beyond the nectarium; from the border of the nectarium arise six long slender stamina, terminated by oblong summits which are prostrate, and in the centre arises a style the length of the stamina, terminated by an obtuse stigma.

Mr. Miller, in his figures, has added some particulars. The root resembles that of the Squill, but is less, covered with a brown skin, and white within, the coats pellucid and gently striped, viscid or full of a clammy juice, bitter to the taste without acrimony. Leaves seven or eight from full-grown roots, twelve or fourteen inches long, flat, of a gray colour, rounded at the ends. The sheath divides into two parts, which turn back. The nectarium is cut at top into ten segments, which spread open. The long filaments are incumbent on the petals. The seeds are black.

[Linnæus remarks, that the petals are lanceolate, with a green line underneath; the three outer hooked inwards at the tip. The angles of the nectary two-parted, acuminate, the length of the filaments, and divaricating to the breadth of the petals. The middle germs of the umbel sessile. Style declining. Filaments bent in.

Cavanilles thus describes it. Bulb subglobular, three inches in diameter, with a brown skin, composed within of thick white coats full of juice. From the base arise many filiform whitish fibres. Scape a foot and half high, cylindric-compressed, very smooth, green, terminated by an umbel of flowers. Leaves linear and channelled, with a blunt back, embracing at the base, from four to seven in number. Spathe deeply bifid, the divisions concave-lanceolate, almost equal, shrivelling; from their centre proceed from seven to twelve rays, separated by very short acute bractes. Corolla superior, funnel-shaped: tube green, round, three or four inches long: border six-cleft; segments white, lanceolate, spreading, with a green dorsal nerve. At the top of the tube and at the origin of the segments there is a subcylindric white body, an inch long, with a spreading, twelve-cleft mouth, supporting the six stamens. Filaments awl-shaped, yellowish, planted between the segments, and running along the inside to the base. Anthers yellow, oblong, twin. Germ inferior, ovate-three-cornered: style simple, filiform, sheathed by the tube of the corolla, a little longer than the stamens, white, scarcely declining: stigma obscurely three-cornered. Capsule ovate-three-cornered, three-celled, three-valved. Seeds compressed, imbricate in three rows round the base of the style.

Native of the South of Europe, as in Spain about Valencia, &c. on the coast; found by Clusius near Montpellier; by Ray near Naples and in Sicily. Cultivated in 1629, by Mr. John Parkinson [1].

Cavanilles remarks, that the leaves are too broad in Miller's figure, as they might well be in a garden specimen: Clusius's small figure observes the proportion of the parts: but that his own is in due size and proportion both. He informs us also from Clusius, that this plant very seldom flowers, when it is removed from its native soil, and then only when the flower is formed in the bulb.

Mr. Salisbury makes not only the *P. maritimum* of Linnæus and Cavanilles (whose figure he condemns) synonimous with his *maritimum*; but also the *carolinianum* of Linnæus, and the *verecundum* of the Kew catalogue. He describes it as a plant a foot and half in height. Leaves six or seven, bifarious, sheathing at the base, from upright spreading, more or less twisted, linear, quite entire, blunt, smooth on both sides with a glaucous tinge, a little striated, flattish, fleshy. Flowers sweet, from six to ten in a bunch. Peduncle (or scape) pale glaucous, from one side among the leaves, erect, compressed, blunt not ancipital, even. Germ pedicelled, oval, three-cornered. Tube of the corolla pale green, cylindrical, angular at top: border snow-white, a little shorter than the tube, from spreading-recurved: segments from the cleft to the middle fastened to the crown, with the sides reflex at bottom, linear-lanceolate, quite entire, bluntly mucronate. Crown (or nectary) snow-white, a little shorter than the border, funnel-shaped, spreading at the tip, grossly two-toothed at the sinuses, even, shrivelling. Filaments very short, scarcely higher than the teeth of the crown, incurved, awl-shaped.

Mr. Salisbury remarks that it seldom flowers when cultivated, which agrees with what was observed above by Cavanilles from Clusius. He gathered it on the sandy coast below Montpellier in 1786 [2].

5. Leaves tongue-shaped, sharp at both ends, quite entire, shining, erect, three feet long, three or four inches wide. Scape the length of the leaves, very much compressed, ancipital, an inch and half wide, green, the whole always prostrate. Spathe twelve-flowered or thereabouts. Flowers sweet, white, sessile, almost half a foot in diameter, with the segments slightly exceeding the tube; nectary an inch long: filaments the length of the corolla [3].

Mr. Salisbury, disliking Jacquin's trivial name, because several other species have a *declinate* scape, when in fruit; and also the younger Linnæus's, of *erectum*, has given this species the name of *amœnum*, and refers Commelin's figure in t. 87. to this, which Linnæus applied to his *caribæum*. According to him, the plant is two feet high. Leaves nine to twelve, green, bifarious, sheathing at the base, recurved, lanceolate, quite entire, bluntish, smooth on both sides, finely streaked, channelled, keeled at the base, fleshy. Flowers fragrant, from ten to fifteen in a bunch. Peduncle (or scape) pale glaucous, among the inner leaves, a little shorter, at first upright, but after flowering bent down, very much compressed and ancipital, smooth with a bloom, a little streaked, solid. Germ bright green, sessile, oval, three-cornered, smooth. Tube of the corolla pale green, two inches and a half long, roundish, thickly streaked: border snow-white, longer by half than the tube, recurved: segments almost equal, linear, quite entire, bluntly mucronate, when expanded equally concave, the sides a little doubled in at the base. Crown snow-white, a little more than two-thirds shorter than the border, funnel-shaped, more contracted at the base than the tube, with the sinuses generally produced into a bifid ligule, somewhat wrinkled, thin, even, shrivelling. Filaments twice as high as the crown [4].

Probably native of Cayenne. Cultivated in gardens at Martinico [5].]

6. This has a roundish bulbous root, covered with a light brown skin, from which arise several narrow dark green leaves, about a foot long: among these comes out a thick stalk (scape) about nine inches high, sustaining six or seven white flowers, with very narrow petals, having large bell-shaped nectariums or cups, deeply indented on their brims. The stamens do not rise far above the nectarium.—Mr. Catesby discovered it in moist boggy soils in Georgia.

[Native of Jamaica and Carolina [6]. Cultivated in 1759, by Mr. Miller [7].—According to Mr. Salisbury, this is not different from *maritimum*.]

7. This has a large bulb, covered with a dark skin, sending out many thick strong fibres, striking deep in the ground. Leaves a foot and half long and two inches broad, of a grayish colour. Scapes thick, succulent, near two feet high. Flowers six or seven,

[1] Hort. kew.
[2] Linn. transf. 2. 70. [3] Jacqu. amer. [4] Linn. transf. 2. 71 [5] Jacquin. [6] Linn. [7] Hort. kew.

white, ſhaped like thoſe of *maritimum*, but with a ſhorter tube, and much longer ſtamens. It flowers in june, and frequently produces ſeeds, which ripen in ſeptember.

[Linneus obſerves, that the leaves are the ſame ſize with thoſe of the Snow-drop.

Native of the South of Europe. Cultivated in 1615, by Mr. John Parkinſon [a].] Mr. Miller ſays, it grows naturally in Sclavonia and Sicily.

According to Mr. Saliſbury, Linneus confounded this with another ſpecies, which Jacquin has named *litterale*. Mr. S. names it *ſtellare*, and applies the ſynonyms of Miller in his figures and of Cluſius which are given to *maritimum*, and of Seba, which is attributed to *illyricum*. He figures it in t. 14. and thus deſcribes it.—Plant a foot high or more. Leaves commonly ſix, glaucous, bifarious, ſheathing at the baſe underground, from erect-recurved, narrow ſpatule-ſhaped, quite entire, blunt, ſmooth with a bloom, very finely ſtreaked, concave, ſomewhat ſucculent. Flowers ſweet, from ſeven to fifteen in a bunch. Peduncle (ſcape) pale glaucous, among the leaves on one ſide, ſolitary, but ſometimes a ſecond from a different axil, erect, very much compreſſed and ancipital, declining when in fruit. Germ pedicelled, oval, triangular. Tube of the corolla pale green, triangular: border white, longer than the tube, ſpreading very much: ſegments lanceolate, flattiſh, the inner narrower. Crown white with a yellow bottom, ſpreading out handſomely like a ſtar, more contracted at the baſe than the tube, much ſhorter than the border, with the ſinuſes deeply biſid, even, ſhrivelling. Filaments double the height of the crown or thereabouts.

It grows wild on the ſandy coaſt of the Iſle of Ree near Rochelle, according to Moriſon. It leafs in april, flowers in june, and the leaves wither at the end of auguſt [b].

8. Bulb the ſize of the fiſt. Leaves enſiform, quite entire, acute, ſhining, ſpreading, deep green, three or four feet long, ſcarcely an inch and half in breadth, imbricate at the baſe and diſtich, embracing each other. Scape two feet high, very much compreſſed, an inch wide on one ſide, ancipital, ſhining, green with a glaucous bloom, axillary, erect or ſometimes declining. Spathe ten-flowered or thereabouts. Flowers handſome, ſpreading, ſeſſile at the top of the ſcape, having an agreeable aromatic odour. Tube of the corolla pale green, round, ſlender, ſlightly widening at the baſe, eight inches long: border white; diviſions linear, channelled, quite entire, ſpreading very much, three inches long, with the tips more or leſs thickened and ſolid. Nectary bell-ſhaped, eroſe-emarginate, one-third of the length of the ſegments of the corolla, ſpreading, white. Filaments awl-ſhaped, ſpreading, green, ſhining, not exceeding the border of the corolla. Anthers orange-coloured.

Found abundantly on the ſandy coaſt of the iſland of Tierra Bomba near Carthagena, by Nic. Joſ. Jacquin [c].

According to Mr. Saliſbury it is three feet high or more. Leaves nine to twelve, from erect-recurved, linear-lanceolate, bluntiſh, ſmooth on both ſides, convex, keeled towards the baſe, fleſhy. From ſeven to ten flowers in a bunch. Scape among the lower leaves, and a little ſhorter, erect in flowering time, afterwards declining, ſtriated, ſolid. Germ ſeſſile, oblong, three-cornered, ſmooth. Tube of the corolla obſcurely three-cornered, ſtriated a little: border ſhorter by half than the tube, recurved; diviſions almoſt equal, bluntly mucronate, faſtened to the crown at the baſe, concave. Crown ſnow-white, ſhorter by two-thirds than the border, funnel-ſhaped, about the ſame diameter with the tube at the baſe, ſpreading wide at top, repand or eroſe in the ſinuſes, ſomewhat wrinkled, even, ſhrivelling. Filaments one and a quarter higher than the crown. In the Species Plantarum it is confounded with the *illyricum*, and hence has ſometimes gone under that name [d].

9. Leaves a foot and half long, half an inch wide. Scape erect, compreſſed, a foot high. Spathes oblong-lanceolate, acuminate, whitiſh, ſhrivelling; the outer larger, an inch and half in length. Flowers fragrant, on three-cornered pedicels, ſcarcely half an inch long. Corolla one-petalled: tube cylindric-three-cornered, greeniſh, ſcarcely two inches long, the thickneſs of a ſwan's quill: border bell-ſhaped, ſix-parted; ſegments acute, a little ſhorter than the tube, ſnow-white, greeniſh on the outſide in the middle. Nectary bell-ſhaped, ſhorter than the ſegments of the corolla, ſix-cleft; the ſegments biſid. Style declining, greeniſh. Stigma obſcurely three-lobed.

Native of the Eaſt Indies. Cultivated in 1776, by Mrs. Theobald. It flowers from june to auguſt [a].]

10. Bulb oblong, white, ſending out ſeveral thick fleſhy fibres, which ſtrike downward. Leaves on very long footſtalks, ſome ovate, others heart-ſhaped, about ſeven inches long and five broad, ending in points, having many deep longitudinal furrows; they are of a light green, and their borders turn inwards. Stalk thick, round and ſucculent, riſing near two feet high, ſuſtaining at the top ſeveral white flowers, ſhaped like thoſe of the other ſorts, but the petals are broader, the tube is ſhorter, and the ſtamens are not ſo long as the petals. There is a thin ſheath, which ſplits open longitudinally.—Native of Amboyna.

P. americanum grows naturally in the iſlands of the Weſt Indies, where it is called *White Lily*. This has a pretty large bulb, a little flatted at the top, covered with a brown ſkin. Leaves near a foot and half long, and little more than an inch broad, dark green, and hollowed in the middle like the keel of a boat. Stalks near two feet high, thick, ſucculent, ſuſtaining at the top eight or ten white flowers, ſhaped like thoſe of *maritimum*, but of a purer white, and having a ſtrong ſweet odour, like that of Balſam of Peru. Stamens very long, ſpreading out wide each way. Piſtil of the ſame length. The flowers ſeldom continue longer than three or four days, and in very hot weather not ſo long. When theſe fade, the germs, which are at the bottom of the tubes, turn to ſo many oblong bulbs, which are irregular in form, and when ripe, drop off in the ground, where they put out fibres and become plants.

P. latifolium alſo grows naturally in the Weſt Indies, where it is not diſtinguiſhed from the preceding. This however differs from it, in the leaves being much longer and broader than that; for theſe are near two feet long and more than three inches broad; hollowed like the keel of a boat, like the other. The flowers are larger, the petals longer, and the ſcent not ſo ſtrong as that of the former. The roots flower in every ſeaſon of the year.

Cultivated by Mr. Miller in 1759.

Mr. Miller has added another ſort in his laſt quarto edition of 1771, which he names *P. ovatum*. This alſo grows naturally in the Weſt Indies, and has a large, roundiſh bulb, from which ariſe ſeveral ovate leaves, about a foot long, and ſix inches broad in the middle, drawing to a point at both ends; they are of a deep green, and have many longitudinal furrows. The ſtalk is thick and ſucculent, a foot and half high, ſuſtaining at the top ſix or eight white flowers, of an agreeable ſweet ſcent, ſmaller than thoſe of the preceding, (*americanum*); the petals are narrower, the tubes ſhorter, and ſo are the ſpathes.

Cultivated by Mr. Miller in 1771.

[Mr. Saliſbury's fourth ſpecies figured in t. 12. and deſcribed in p. 73. is entitled *ſpeciosum*. His ſpecific character is this—petioles narrow, tube of the corolla triangular, thinly ſtriated; ſegments longer than the tube, ſpreading and recurved a little, linear, alternately more concave, ſinuſes of the crown with a biſid ligule or proceſs.—He thus deſcribes it: Plant a foot and half high. Leaves nine to twelve, green, bifarious. Petioles narrow, ſheathing with the widened baſe, recurved, linear, half round, flat above. Leaves three times as long as the petioles, recurved, lanceolate, quite entire, blunt, ſtriated, ſomewhat concave, keeled

[a] Hort. kew. [b] Linn. tranſ. 2. 74. [c] Jacqu. amer. [d] Linn. tranſ. 2. 74.

[a] Hort. kew.

towards the base, smooth above, even beneath, fleshy. Flowers fragrant, from eleven to fifteen in a close bunch. Peduncle or scape pale green, among the lower leaves, than which it is a little shorter, much wider than in the rest, erect in flowering time, but afterwards declining, compressed, with one side flatter, ancipital, smooth, very finely striated, solid. Interior bractes very wide. Germ pedicelled, suboval, triangular, smooth. Tube of the corolla three inches long, cylindrical, triangular, thinly striated, abounding in nectareous juice: border snow-white, longer by half than the tube, spreading and a little recurved; segments nearly equal in breadth, linear, quite entire, the exterior longer and more concave, and also more pointed. Crown snow-white, twice and a half shorter than the border, funnel-shaped, more contracted at the base than the tube, in the middle of the sinuses produced into a wedge-shaped ligule usually bifid, somewhat wrinkled, even, shrivelling. Filaments once and a half higher than the crown. This species is distinguished at first sight by the width of the interior bractes.

Mr. Salisbury does not mention the native country of this species: but says that it has hitherto flowered in his stove only in the month of october [1].

PROPAGATION AND CULTURE.

The sorts of the East and West Indies are too tender to thrive in England out of a good stove. If the pots be plunged into the bark bed, they will thrive and flower very well. In the dry stove, their flowers will not be so strong, nor will they appear oftener than once a year; whereas in the tan-bed, they will often flower two or three times. They are propagated by offsets from the roots, or by the bulbs which succeed the flowers. If the latter be planted in small pots filled with light earth from a kitchen garden, and plunged into a moderate hot-bed, they will soon put out roots and leaves, and with care will become blowing roots in one year: if these are kept constantly in the tan-bed, they will put out offsets from the roots, and thrive as well as in their native countries.

4. Sea Pancratium must be planted in a very warm border, and screened from severe frost, otherwise it will not live through the winter in England.

7. This sort is hardy, and will thrive through the winter in the full ground; in very severe seasons the surface should be covered with tanner's-bark, sea-coal ashes, straw, or peas-haulm. It is propagated either by offsets from the roots, or from seeds. The offsets will flower very strong the second year, whereas those which are raised from seeds seldom flower in less than five years.

The roots should not be removed oftener than every third year, if they be expected to flower strong. The best time to transplant them is in the beginning of october, soon after their leaves decay. They should not be kept long out of the ground, for as they do not lose their fibres every year, if these are dried, it greatly weakens the roots. It loves a light sandy soil, and a sheltered situation; the roots should be planted nine inches or a foot asunder every way, and five inches deep in the ground.

If the plants are propagated by seeds, they should be sown in pots filled with light earth soon after they are ripe: these pots should be placed under a hot-bed frame in winter, but the glasses must be taken off every day in mild weather. For the other management see NARCISSUS: only the young roots will require a little protection in winter, till they have obtained strength.

DESCRIPTION, *&c.*

Now and then a plant may be found with a single and pretty erect trunk of ten feet in height, and a branching round head; but it is generally in form of a very large, branching, spreading bush. From the stems or larger branches issue large carrot-shaped blunt roots, descending till they come to the ground, and then dividing. The substance of the most solid is something like that of a cabbage stalk, and by age acquires a woody hardness on the outside. Leaves confluent, stem-clasping, closely imbricated in three spiral rows, round the extremities of the branches, bowing, from three to five feet long, tapering to a very long fine triangular point, very smooth and glossy, margins and back armed with very fine sharp spines; those on the margins point forward, those of the back point sometimes one way, sometimes the other.

Male flowers are in a large, pendulous, compound, leafy raceme, the leaves of which are white, linear-oblong, pointed and concave; in the axil of each, there is a single thyrse of simple small racemes of long-pointed depending anthers; they are not sessile, but raised from the rachis of the raceme by tapering filaments.

Female flowers, on a different plant, terminating and solitary, having no other calyx or corolla than the termination of the three rows of leaves forming three imbricated fascicles of white floral leaves, like those of the male raceme, which stand at equal distances round the base of the young fruit. Germs numerous, collected in firm wedge-shaped angular bundles of from six to ten or more, forming the compound germs of the future drupes, closely impacted round the receptacle. Style none. Stigma single, oval, grooved lengthwise, yellow, affixed to the outside of a two-lipped umbilicus on the apex of the germ. Fruit compound, oval, from five to eight inches in diameter, and from six to ten in length, weighing from four to eight pounds, rough, of a rich orange colour composed of numerous wedge-shaped angular drupes; when ripe, their large or exterior ends are detached from one another, and covered with a firm deeper orange-coloured skin; apices flat, consisting of as many angular somewhat convex tubercles as there are cells in the drupe, each crowned with the withered stigma internally; the exterior half of these drupes, next the apex, consists of dry spongy cavities, their lower part next the core or common receptacle is yellow, consisting of a rich-looking yellow pulp, intermixed with strong fibres; here the nut is lodged.

This

This is compound, top-ſhaped, exceedingly hard, angular, containing as many cells as there are diviſions on the apex of the drupe; each cell is perforated above and below. Seed ſingle, oblong, ſmooth, adhering lengthwiſe to a ſmall faſcicle of ſtrong white fibres, which paſs through the perforation of the cell. By far the greater number of theſe cells are barren.

It is a native of the warmer parts of Aſia. All ſoils and ſituations ſeem to ſuit it equally well: it flowers chiefly during the rainy ſeaſon.

This plant is much employed there for hedges, and anſwers well, but takes much room. It grows readily from branches, whence it is rare to find the full-grown ripe fruit.

The tender white leaves of the flowers, chiefly thoſe of the male, yield that moſt delightful fragrance, for which they are ſo generally eſteemed; and of all the perfumes it is by far the richeſt and moſt powerful.

The lower yellow pulpy part of the drupe is ſometimes eaten by the natives in times of ſcarcity and famine. The tender white baſe of the leaves is alſo eaten raw or boiled at ſuch melancholy times. The taſte of the pulpy part of the drupe is very diſagreeable.

The roots are compoſed of tough fibres, which baſket-makers uſe to tie their work with; they are ſo ſoft and ſpongy as to ſerve the natives for corks: the leaves alſo are compoſed of longitudinal, tough, uſeful fibres.

It is not cultivated in the Eaſt Indies with any other view than for fences[2].

In the Supplement of the younger Linneus it is ſaid, from Forſkahl and Thunberg, to be cultivated for the ſake of its fragrance.

In the South Sea iſlands, where the Pandanus is alſo a native, this or ſome other ſpecies or variety is uſed for making mats. The leaves are beautifully white and gloſſy. In the Sandwich iſlands theſe mats are handſomely worked in a variety of patterns, and ſtained of different colours. The branches being of a ſoft ſpongy juicy nature, cattle will eat them very well, when cut into ſmall pieces. They call it *Wharra Tree* at Otaheite[3].

Mugalie is the Telinga name of the male plant, and *Gbæzangee* that of the female. *Caldera* is the name they are known by amongſt Europeans on the coaſt of Coromandel[4].

It grows alſo in China and Cochinchina, according to Loureiro, and is uſed for hedges and feeding tame elephants, &c. Its fragrance is not in much eſteem there.

Forſter ſays that the fruit in Otaheite is called *e-Vara*, and the male flowers *Hinanno*: that it is found of ſandy coaſts, and is found on almoſt all the iſlands of the Southern ocean, within the tropics, even on thoſe which are occaſionally inundated; that it reſembles the Ananas in the fruit and leaves, and may be connected with the Palms with more propriety than Stratiotes and Vallisneria; that it is cultivated in Arabia and Ceylon on account of the fragrancy of the male flowers; that the women in India, eſpecially on the iſlands, powder their hair with the duſt of the anthers, which is very fragrant, and that they lay up the floral leaves and bunches of flowers among their clothes; that in Ternate they dreſs the flowers before they open as ſauce for fleſh and fiſh; that in Banda they lay the leaves on wounds; that in India the fruit is eaten by elephants, in Otaheite and the neighbouring iſlands by children, and when bread-fruit is ſcarce, even by grown perſons; and that it has a fine aromatic ſcent like the Strawberry or the Pine-apple, a taſte at firſt ſweetiſh, but afterwards aſtringent and auſtere.

He mentions four varieties figured in the Hortus Malabaricus, t. 5, 6, 7, 8. and ſays that ſome varieties have no fragrance[5].—Loureiro has diſtinguiſhed two other ſpecies—*humilis*, hort. malab. t. 6. and *levis*. Rumph. amb. p. 147.

It was introduced into England in 1771, by Monſ. Richard, but has not yet flowered in our ſtoves[6].

Spikes alternate directed one way awnless ovate rugged, rachis roundish.

16. Panicum fluitans. *Floating Panic-grass.*
Lin. spec. ed. Willd. 338. *Retz. obs.* 3. 8. & 5. 18. *Vahl symb.* 1. 8. *Pluk. amalth. t.* 417. *f.* 7.

P. geminatum. *Forst. descr.* 18. *n.* 59.

Spikes alternate sessile directed one way, the third calycine valve minute.

17. Panicum brizoides. *Briza-like Panic-grass.*
Lin. syst. 105. *Reich.* 1. 155. *Willd.* 338. *mant.* 184. *Swartz obs.* 36 ? *Retz. obs.* 5. 18. *Pluk. phyt. t.* 191. *f.* 1.

Spikes alternate sessile directed one way, two of the calycine valves much shorter than the corolla and retuse, the third the same length with the corolla.

18. Panicum flavidum. *Yellowish Panic-grass.*
Lin. spec. ed. Willd. 339. *Retz. obs.* 4. 15.

Culm leafy, spikelets remote sessile pressed close directed one way few-flowered.

19. Panicum dimidiatum. *Half-spiked Panic-grass.*
Lin. syst. ed. 13. 90. *Reich.* 1. 156. *Willd.* 339. *Retz. obs.* 6. 23. *Burm. ind.* 25. *t.* 8. *f.* 5.

Spike halved and directed one way, spikelets five-flowered, alternately pressed to the hollowed rachis.

20. Panicum Burmanni. *Wave-leaved Panic-grass.*
Lin. spec. ed. Willd. 339. *Retz. obs.* 3. 10. *Becc. muf.* 2. 66. *t.* 55.

P. hirtellum. *Burm. ind.* 24. *t.* 12. *f.* 1.

P. undulatifolium. *Ard. spec.* 2. 14. *t.* 4.

Spikes mostly four remote directed one way simple, the two outer glumes of the flowers awned.

21. Panicum hirtellum. *Rough-haired Panic-grass,* or *Scotch-grass.*
Lin. spec. 83. *syst.* 105. *Reich.* 1. 156. *Willd.* 340. *amoen.* 5. 391. *Swartz. obs.* 35. *Brown. jam.* 133. 2. *Colliuson app.* 13.

Spike compound, spikelets pressed close alternate, calyxes doubled, all the valves awned, outer longest.

22. Panicum pilosum. *Hairy Panic-grass.*
Lin. spec. ed. Willd. 340. *Swartz prodr.* 22. *descr.* 141. *Sloan. jam.* 1. 114. (Milium).

Spikes panicled alternate directed one way, spikelets in pairs, one smaller, acuminate, even, rachis compressed hairy, culm divaricate jointed.

23. Panicum molle. *Soft Panic-grass.*
Lin. spec. ed. Willd. 340. *Swartz prodr.* 22. *descr.* 143. *Brown. jam.* 133. 1.

Spikes panicled alternate directed one way spreading, spikelets approximating pedicelled directed one way awnless.

24. Panicum fasciculatum. *Fascicled Panic-grass.*
Lin. spec. Willd. 341. *Swartz prodr.* 22. *descr.* 145.

Spikes panicled alternate erect subfastigiate, spikelets directed one way roundish.

25. Panicum carthaginense. *Carthagena Panic-grass.*
Lin. spec. Willd. 341. *Swartz prodr.* 22. *descr.* 148.

Spikes panicled, leaves shorter, spikelets directed one way roundish.

26. Panicum conglomeratum. *Conglomerate Panic-grass.*
Lin. syst. 106. *Reich.* 1. 156. *Willd.* 341. *mant.* 324.

P. indicum. *Lin. mant.* 184. *Retz. obs.* 3. 9.

Aira indica. *Lin. spec.* 94.

Spike directed one way subovate, florets blunt.

27. Panicum interruptum. *Broken-spiked Panic-grass.*
Lin. spec. ed. Willd. 341.

P. caudatum. *Thunb. prodr. cap.* 19?

Spike simple interrupted, spikelets two-flowered pedicelled naked.

28. Panicum sanguinale. *Slender-spiked Cock's-foot Panic-grass.*
Lin. spec. 84. *syst.* 106. *Reich.* 1. 157. *Willd.* 342. *Hudf. angl.* 25. *Wither. arr. ed.* 3. 115. *Curt. lond.* 4. 7. 242. *Fl. dan. t.* 388. *Schreb. gram.* 119. *t.* 16. *Pollich pal. n.* 60. *Gron. virg.* 154. *Burm.*

Gr. cartarium ischæmi paniculis. *Park. theat.* 1179. 5.

Gr. dactyloides radice repente. *Ger. emac.* 28. 3.

Spikes digitate spreading, villose at the base on the inside, flowers solitary, runners creeping.

30. Panicum umbrosum. *Shady Panic-grass.*
Lin. spec. ed. Willd. 343. *Retz. obs.* 4. 16.

Spikes about four remote, florets in pairs unequally pedicelled, culm creeping flaccid.

31. Panicum filiforme. *Filiform-spiked Panic-grass.*
Lin. spec. 85. *Reich.* 1. 158. *Willd.* 343. *Thunb. jap.* 48.

Spikes subdigitate approximating erect filiform, rachis flexuose, teeth two-flowered, one sessile, inner valve very small, culm and leaves smooth.

32. Panicum ægyptiacum. *Egyptian Panic-grass.*
Lin. spec. ed. Willd. 343. *Retz. obs.* 3. 8.

P. filiforme. *Jacqu. obs.* 3. 18. *t.* 70.

Spikes subdigitate approximating erect filiform, rachis flexuose, teeth two-flowered, flowers pedicelled, inner valve three-nerved, culm and leaves hairy.

33. Panicum ciliare. *Ciliated Panic-grass.*
Lin. spec. ed. Willd. 344. *Retz. obs.* 4. 16.

Spikes subdigitate approximating erect filiform, rachis flexuose, teeth two-flowered, flowers pedicelled, outer valve ciliate, culm and leaves hairy.

34. Panicum lineare. *Linear-spiked Panic-grass.*
Lin. spec. 85. *syst.* 106. *Reich.* 1. 158. *Willd.* 344. *Retz. obs.* 3. 10. *Burm. ind.* 25. *t.* 10. *f.* 3. *Sloan. jam.* 1. 113. *n.* 28. *t.* 70. *f.* 3. (Gramen dactylon).

Spikes digitate in fours or thereabouts linear, florets solitary directed one way awnless.

35. Panicum cimicinum. *Bug Panic-grass.*
Lin. spec. ed. Willd. 344. *Retz. obs.* 3. 9.

Milium cimicinum. *Lin. mant.* 184.

Panicle umbelled, racemes in fours, one of the calycine glumes ciliate.

36. Panicum distachyon. *Distich-spiked Panic-grass.*
Lin. syst. 106. *Reich.* 1. 158. *Willd.* 345. *mant.* 138. *Retz. obs.* 5. 17.

Spikes in pairs directed one way even—three or four. R.

37. Panicum squarrosum. *Scaly Panic-grass.*
Lin. spec. ed. Willd. 345. *Retz. obs.* 4. 15. & 5. *t.* 1.

Cenchrus muricatus. *Lin. mant.* 302. *Schreb. gram.* 2. 69. *t.* 34.

Spikes in pairs horizontal, involucres of the flowers squarrose, culms decumbent.

38. Panicum hispidulum. *Hispid Panic-grass.*
Lin. spec. ed. Willd. 346. *Retz. obs.* 5. 18.

Spikes binate and ternate erect, calyxes hispid two-awned.

39. Panicum compositum. *Compound-spiked Panic-grass.*
Lin. spec. 84. *syst.* 106. *Reich.* 1. 159. *Willd.* 346. *fl. zeyl. n.* 42.

Spike compound, spikelets linear directed one way, florets in pairs remote, calyxes awned.

40. Panicum elatius. *Tall Panic-grass.*
Lin. syst. 106. *Willd.* 346. *suppl.* 107.

Spike compound, spikelets oblong scattered pressed close, florets crowded, calyxes mucronate-awned.

** *Panicled.*

41. Panicum dichotomum. *Dichotomous Panic-grass.*
Lin. spec. 85. *Reich.* 1. 159. *Willd.* 346. *Gron. virg.* 133.

Panicles simple, culm branched dichotomous.

42. Panicum ramosum. *Branched Panic-grass.*
Lin. syst. 106. *Reich.* 1. 159. *Willd.* 346. *mant.* 29.

Panicle with simple branches, flowers in threes or thereabouts, lower subsessile, culm branched.

43. Panicum deustum. *Burnt Panic-grass.*
Lin. spec. ed. Willd. 347. *Thunb. prodr. cap.* 19.

Panicle spreading, flowers solitary, glumes smooth purple at the tip.

44. Panicum coloratum. *Coloured Panic-grass.*
Lin. syst. 106. *Reich.* 1. 159. *Willd.* 347. *mant.* 30. *Jacqu. misc.* 2. 365. *icon. rar.* 1. *t.* 12.

Panicle spreading, flamens and pistils coloured, culm branched—quite simple. Jacqu.

45. Panicum repens. *Creeping Panic-grass.*
Lin. spec. 87. *syst.* 106. *Resch.* 1. 160. *Willd.* 347.

Panicle rod-like, leaves divaricating.

46. Panicum Ischæmoides. *White Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 17.

Panicle erect contracted, calyxes two-flowered polygamous acute, culm simple, leaves distich rigid.

47. Panicum remotum. *Distant Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 17.

Branches of the panicle three-sided, florets subgeminate one pedicelled, culm branched four-cornered compressed.

48. Panicum stipulatum. *Awned Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 17.

Culm creeping rooting, branches of the panicle undivided, florets in pairs sessile awned.

49. Panicum miliaceum. *Millet Panic-grass.*
Lin. spec. 86. *syst.* 106. *Reich.* 1. 160. *Willd.* 348. *hort. cliff.* 27. *upf.* 20. *mat. med.* 46. *Leur. cochinch.* 47. *Hoffm. germ.* 22. *Roth. germ.* 1. 28. 2. 75. *Krock. filef. n.* 99. *Plenck, ic.* 42.]

Milium panicum. *Mill. dict. n.* 1.

M. semine luteo [& albo, item nigro. *Baub. pin.* 26. *theat.* 502. *Retz. obs.* 1. 11.

Milium. *Baub. hist. Dod. pempt.* 506. *Ger.* 73. 1. *emac.* 8. *Raii hist.* 1251. 1, 2.—& nigrum. *Ger.* 73. 2.

M. vulgare album. *Park. theat.* 1136. 1.

β. M. attenuatum. *Moench. meth.* 204. (excl. syn.)

Panicle loose flaccid, sheaths of the leaves rough-haired, glumes mucronate nerved.

50. Panicum antidotale. *Medicinal Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 17.

Panicle nodding, calyxes two-flowered polygamous acute, culm erect very much branched.

51. Panicum notatum. *Black-spotted Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 18.

Panicle spreading, axils marked, leaves lanceolate ciliate.

52. Panicum muricatum. *Muricated Panic-grass.*
Lin. spec. ed. Willd. 348. *Retz. obs.* 4. 18.

Panicle spreading, flowers solitary muricated, culm rooting ascending.

53. Panicum capillare. *Capillary Panic-grass.*
Lin. spec. 86. *syst.* 106. *Resch.* 1. 160. *Willd.* 349. *Retz. obs.* 3. 9. *Gron. virg.* 13.

Milium indicum panicula ſparſa erecta. *Tournef. inſt.* 515.

Panicle capillary erect ſpreading, peduncles ſtrict, calyxes acuminate even, ſheaths of the leaves very hirſute.

54. Panicum flexuoſum. *Flexuoſe Panic-graſs.*
Lin. ſpec. ed. Willd. 349. *Retz. obſ.* 3. 9.
β. totum glabrum. *Retz. obſ.* 4. 16.
Panicle capillary ſpreading, peduncles flexuoſe, calyxes ovate, beard of the joints reflex.

55. Panicum groſſarium.
Lin. ſpec. 86. *ſyſt.* 107. *Reich.* 1. 160. *Willd.* 349. *amoen.* 5. 392. *Thunb. jap.* 48.
P. repens. *Burm. ind.* 26. *t.* 11. *f.* 1?
Branches of the panicle ſimple, flowers in pairs with one of the pedicels very ſhort, the other the length of the flower.

56. Panicum maximum. *Large Panic-graſs,* or *Guinea-graſs.*
Lin. ſpec. ed. Willd. 349. *Jacqu. ic. rar.* 1. *t.* 13. *collect.* 1. 76. *Swartz deſcr.* 170. *Brown. jam.* 366. *n.* 2. (Holcus).
P. polygamum. *Swartz prodr.* 24. *Lin. ſpec. ed. Willd.* 353.
Panicle compound capillary ſpreading, branches racemed, knots of the joints and ſheaths hirſute at the baſe.

57. Panicum nemoroſum. *Wood Panic-graſs.*
Lin. ſpec. ed. Willd. 350. *Swartz prodr.* 22. *deſcr.* 150.
Panicle ſimple, branches diſtant erect, florets remote ſcattered ovate acuminate, culm decumbent jointed, ſheaths and neck hairy.

58. Panicum acuminatum. *Sharp leaved Panic-graſs.*
Lin. ſpec. ed. Willd. 350. *Swartz prodr.* 22. *deſcr.* 152.
Panicles ſimple ſhorter than the leaves, branches capillary diffuſed, ſpikelets remote obovate, culm decumbent jointed branched, leaves lanceolate-ſubulate, erect, ſheaths villoſe.

59. Panicum rigens. *Stiff-panicled Panic-graſs.*
Lin. ſpec. ed. Willd. 350. *Swartz prodr.* 23. *deſcr.* 154.
Panicle ſimple rigid ſpreading, culm branched decumbent, leaves horizontal rugged.

60. Panicum fuſcum. *Brown Panic-graſs.*
Lin. ſpec. ed. Willd. 350. *Swartz prodr.* 23. *deſcr.* 156.
Panicle ſimple, branches erect, florets directed one way in pairs, one on a ſhorter pedicel, culm erect ſubdivided, leaves broad-lanceolate.

61. Panicum laxum. *Looſe Panic graſs.*
Lin. ſpec. ed. Willd. 350. *Swartz prodr.* 23. *deſcr.* 157. *Sloan. jam.* 1. 114. (Milium).
Panicle ſimple nodding, branches capillary, ſpikelets approximating alternate preſſed cloſe, culms ſimple filiform flaccid, leaves linear-lanceolate.

62. Panicum latifolium. *Broad-leaved Panic-graſs.*
Lin. ſpec. 85. *Reich.* 1. 160. *Willd.* 350. *Mor. hiſt.* 3. 196. *ſ.* 8. *t.* 5. *f.* 4. *Laur. cochinch.* 47.
Panicle with racemes lateral ſimple, leaves ovate-lanceolate hairy at the neck.

63. Panicum flaveſcens. *Yellow Panic-graſs.*
Lin. ſpec. ed. Willd. 351. *Swartz prodr.* 23. *deſcr.* 158.
Panicle ſimple erect ſtiff, branches ſubfaſtigiate, the loweſt oppoſite, ſpikelets approximating directed one way, pedicels two-flowered.

64. Panicum diffuſum. *Diffuſed Panic-graſs.*
Lin. ſpec. ed. Willd. 351. *Swartz prodr.* 23. *deſcr.* 160. *Sloan. jam.* 1. 114. (Milium).
Panicle ſomewhat ſimple capillary ſpreading, ſpikelets diſtant, culm decumbent ſimple, leaves linear hairy at the neck.

65. Panicum oryzoides. *Rice-like Panic-graſs.*
Lin. ſpec. ed. Willd. 351. *Swartz prodr.* 23. *deſcr.* 162.
Panicle almoſt ſimple, branches erect, florets ſomewhat remote ovate acute, culm erect undivided, leaves broad-lanceolate rounded at the baſe, ſheaths even.

66. Panicum clandeſtinum. *Hidden Panic-graſs.*
Lin. ſpec. 86. *Reich.* 1. 161. *Willd.* 351.
Racemes hidden within the ſheaths of the leaves.

67. Panicum arboreſcens. *Tree Panic-graſs.*
Lin. ſpec. 87. *Reich.* 1. 161. *Willd.* 351. *fl. zeyl. n.* 43. *hort. cliff.* 27.
Panicled very much branched, leaves ovate-oblong acuminate.

68. Panicum curvatum. *Crooked-chaffed Panic-graſs.*
Lin. ſyſt. 107. *ed.* 12. 732. *Reich.* 161. *Willd.* 352.
Panicle racemed, glumes curved obtuſe nerved.

69. Panicum virgatum. *Long-panicled Panic-graſs.*
Lin. ſpec. 87. *ſyſt.* 107. *Reich.* 1. 161. *Willd.* 352. *Gron. virg.* 133.
Panicle rod-like, glumes acuminate even, outmoſt gaping.

70. Panicum patens. *Spreading Panic-graſs.*
Lin. ſpec. 86. *ſyſt.* 107. *Reich.* 1. 162. *Willd.* 352.
Panicle oblong flexuoſe capillary ſpreading, calyxes two-flowered, leaves linear-lanceolate, culm rooting.

71. Panicum trigonum. *Triangular-ſeeded Panic-graſs.*
Lin. ſpec ed. Willd. 352. *Retz. obſ.* 3. 9.
P. patens. *Burm. ind.* 26. *t.* 10. *f.* 2.
Panicle erect, peduncles two-flowered, calyxes obtuſe biſpid one-flowered, ſeeds three-cornered.

72. Panicum pallens. *Pale Panic-graſs.*
Lin. ſpec. ed. Willd. 352. *Swartz prodr.* 23. *deſcr.* 164.
Apluda Zeugites. *Aubl. guian.*
Panicle compound ovate, branches cluſtered erect, ſpikelets ovate ſubulate, culm ſubdivided jointed, leaves ovate-lanceolate, ſheaths ciliate on the neck and at the edge.

73. Panicum lanatum. *Woolly Panic-graſs.*
Lin. ſpec. ed. Willd. 353. *Swartz prodr.* 24. *deſcr.* 168.
Panicle compound erect ſmooth, ſpikelets ovate, culm branched, leaves ovate-lanceolate pubeſcent, ſheaths lanuginoſe-hirſute.

74. Panicum arundinaceum. *Reedy Panic-graſs.*
Lin. ſpec. ed. Willd. 353. *Swartz prodr.* 24. *deſcr.* 166.
Panicle compound ſpreading, branches and branchlets ſtiff capillary, ſpikelets roundiſh, culm ſubdivided jointed, leaves broad-lanceolate acuminate rigid.

75. Panicum glutinoſum. *Glutinous Panic-graſs.*
Lin. ſpec. ed. Willd. 353. *Swartz prodr.* 24. *deſcr.* 174. *Sloan. jam.* 1. 114. *t.* 71. *f.* 3. (Gramen miliaceum).
Panicle compound ſpreading, branches flexuoſe, ſpikelets pedicelled diſtant glutinous, culm erect ſimple, leaves broader.

76. Panicum radicans. *Rooting Panic-graſs.*
Lin. ſpec. ed. Willd. 354. *Retz. obſ.* 4. 18.
Panicled, culm branching rooting, the baſe of the leaves and the ſheaths longitudinally ciliate.

77. Panicum trichoides. *Hair-like Panic-graſs.*
Lin. ſpec. ed. Willd. 354. *Swartz prodr.* 24. *deſcr.* 176. *Sloan. jam.* 1. 86. 115. *t.* 72. *f.* 3. *Brown. jam.* 366. 1. (Holcus).
P. breviſolium. *Lin. ſpec.* 87. *ſyſt.* 107. *Pluk. phyt. t.* 189. *f.* 4.
Panicle very much branched ſpreading, branches and branchlets ſubdivided capillary, culm declined jointed, leaves ovate-lanceolate very ſmooth.

78. Panicum divaricatum. *Straddling Panic-graſs.*
Lin. ſyſt. 107. *Reich.* 1. 162. *Willd.* 354. *amoen.* 5. 392.
Panicles ſhort awnleſs, culm very much branched and extremely divaricating, pedicels two-flowered, one ſhorter.

79. Panicum hirſutum. *Shaggy Panic-graſs.*
Swartz deſcr. 173.
Panicle compound capillary, ſpreading, culms and ſheaths briſtly-hirſute, leaves lanceolate acuminate nerved ſtrict.

DESCRIPTIONS, &c.

1. In the ſpikes this reſembles *Panicum glaucum*, but they are only half the ſize, and the piſtils are blood-red. Culm rooting at bottom, from one to ſix feet in height, very much branched. Leaves hairy, at top almoſt oppoſite. Involucrets almoſt ſix times as long as their flowers, purple, with ciliate briſtles from the baſe to the middle with longiſh hairs.—Native of the Eaſt Indies. Biennial*.

* Linn. ſpec. & mant.

Loureiro

Loureiro describes the culm as annual, two feet high, upright, slender, round, jointed. Leaves subulate-linear, long, upright, those next the root in heaps, those on the stem scattered, short, somewhat hairy. Spike cylindrical, erect, simple. Involucres one-flowered, rough with many long bristles in bundles.—Native of Cochinchina.

2. This is an annual grass, native of the West Indies. It was introduced in 1780, by John Earl of Bute It flowers from june to september [a].

3. This in its general habit agrees exactly with *P. viride*; but in the size and form of the spike, and the parts composing it, differs very materially: the whole plant is generally one-third larger; the spike also is larger, and much less compact; it is evidently composed of little branches, which grow somewhat in whorls, whence its name: the bristles of the spike are considerably shorter than those of the *viride*, and differ from them particularly in being hooked, so that the spikes readily adhere to any thing, and where several of them grow near each other they are very apt, from this cause, to become entangled [b].

According to Linnæus, the spike is composed of longer racemes than in *P. viride*, three or four in number, directed one way downwards. Flowers green with purple pistils. Bristles one or two, rugged, to each flower, and longer than that. Pedicels on the falling of the flowers terminated by a truncate, concave, white cup. The rachis of the spike has three or four bifid angles. Culms even, two feet high. Leaves naked. The spike is from two inches and a half to four inches in length, and near half an inch broad [c].

Native of Europe, the Levant, and Japan. In England, Mr. Ray describes it as having been found between Putney and Rochampton, and beyond the neat-houses by the Thames side. Mr. Curtis found it sparingly in the gardener's ground in Battersea field, with the *viride*, and flowering at the same time. Scheuchzer remarks, that it is a troublesome weed in the gardens near Paris [d].

Thunberg describes two varieties, a larger and a smaller; the latter seeming to be distinct.

4. This is an annual grass, bearing a great resemblance to *P. glaucum*, but in reality different. Culm six feet high, branched; barren branches shorter. Leaves towards the base above with white hairs near an inch in length and spreading. Spike simple, a span long, the florets without order. Peduncles scarcely streaked at the tip. Involucrets pale red, one-flowered, many-bristled, longer than the flower. Glume with longitudinal streaks (but no transverse waved ones) green, distinct.—Native of the East Indies [e].

5. Bristles on the spike the length of the florets. Sheaths of the leaves hairy at the edges. When the spike is just come out the flowers appear disposed in rows. Seeds marked with waved streaks [f]. Peduncle very much grooved [g].

Root fibrous, annual. Culms a foot high, erect, leafy, having four knots, grooved at the top, even. Leaves broadish, flat, even, the upper one often longer than the spike. Instead of a ligule there are clustered, whitish, long hairs, especially from the lower sheaths. Sheaths striated, even. Spike as in the next species: the florets disposed in rows, three times as large, subsessile, solitary and in pairs, accompanied by bristles, finally becoming yellow, shorter than in *P. viride*. Calyx nerved, pubescent. Corolla less than the calyx. Third petal ovate, acute, flat, between the flatter valve of the calyx and the inner valve of the corolla; perhaps the rudiment of a second floret. Seed wrinkled with transverse waved streaks [h].

Native of the East Indies, America, and several parts of Europe, as Italy, the South of France, Germany, Switzerland. It flowers in june and july. Introduced in 1771, by Monf. Richard [i].

6. This is distinct enough from the preceding in having smooth seeds, not transversely waved and wrinkled. The glumes are nerved, as in the preceding [k].

[a] Hort. kew. [b] Curtis. [c] Withering. [d] Curt. lond. [e] Linn. suppl. [f] Linn. spec. [g] Linn. syst. [h] Lœrs. [i] Hort: kew. [k] Willdenow.

Scopoli says that the third glume is not always present. Lœrs, that it is always wanting.

Mr. Curtis remarks, that this species, to correspond with its trivial name, should be always green, but that its foliage is often red, and its spikes reddish brown; and that the *verticillatum* is the contrary; but the spike will always distinguish them. Between these two indeed there is a more sensible difference to the touch than between *Alopecurus pratensis* and *Phleum pratense*. The hairs in the spike of the *viride* are much longer than those of the *verticillatum*; and though the microscope discovers them to be prickly, yet being upright, they show no manifest roughness.

Lœrs thus describes it. Root annual. Culms from a foot to eighteen inches in height, oblique, leafy, having three knots, streaked at top, rugged. Leaves widish, the upper surface rugged. Instead of a ligule, a row of short hairs, running down. Sheaths somewhat compressed, even. Spike ovate-cylindrical, unequal in thickness, green, frequently tinged with violet on one side. Peduncles very short, having the florets in pairs (three or four) on scarcely conspicuous, knotted-truncate pedicels: each pair involucred with several whitish or violet bristles, four times as long as the florets. Calyx even: the smaller valve three-nerved, the opposite to this three times as large, embracing a third with its edge, convex, seven-nerved: the third flat, five-nerved. Seed nerved, shining. The third petal of the corolla is found in the preceding, in *Crus-galli* and *miliaceum*, but not in this.—According to Mr. Curtis, the calyx has three valves, two of which are opposite, equal, ovate, obtuse, ribbed; the third very minute and placed below the others: the corolla has two valves, which are ovate, hollow, shining and nearly equal.

He observes, that sparrows are remarkably fond of the seeds, and that the whole of this genus, when cultivated in a garden, require to be protected from them.

Native of Europe, as Germany, Carniola, England. With us not common, though the most common of the Panicums. In Battersea fields, near London; by Martha's chapel, near Guildford in Surry; and in the gravel-pits by Chippenham-park, Cambridgeshire, and the corn fields adjoining.

It flowers in july and august, and is an annual grass of no use in cultivation.

7. This has been confounded with the next species, from which it is distinct, in having the spike not interrupted at the base, smaller and ovate; in the height of the culm; in the shortness of the involucrets; and in having the rachis hirsute [a].

Willdenow says that he has frequently received the seeds of the variety under the names of *P. indicum* and *sibiricum*; that it approaches in habit to *P. verticillatum*, on account of the very short involucrets, sometimes scarcely visible without tearing the spikelets in pieces: but that it differs very much in the hairiness of the rachis, which in P. verticillatum is smooth.]

Mr. Miller says, it rises with a jointed reed-like stalk about three feet high, and about the size of the common Reed; with a leaf at each joint a foot and half long, and about an inch broad at the base where broadest, ending in an acute point, rough to the touch, embracing the stalk at the base, and turning downwards about half the length. The stalks are terminated by compact spikes, about the thickness of a man's finger at bottom, growing taper towards the top, eight or nine inches long, closely set with small roundish grain like that of Millet. It is annual, and perishes soon after the seeds are ripe. There are three varieties of it, with yellow, white and purple grains. It has been formerly cultivated for bread, in some of the northern countries, but is not so much esteemed as the Italian sort; since however it will ripen better in a cold climate than that, it is generally cultivated where a better sort of grain will not succeed: neither of them are reckoned to afford so good nourishment as Millet.

[Native of the southern part of Europe.

[a] Willdenow.

8. Culm annual, a foot and half high, round, thickiſh, upright, quite ſimple. Leaves alternate, lanceolate-linear, flat, ſtriated, reflexed. Spike ſingle, large, reclining, compoſed of glomerate ovate ſpikelets mixed with cloſe briſtles, longer than the floret. Seed yellow, ſubglobular [a].

This riſes with a reed-like ſtalk, near four feet high, and much thicker than that of the preceding; the leaves are alſo broader. The ſpikes are a foot long, and twice the thickneſs of thoſe of the former, but not ſo compact, being compoſed of ſeveral roundiſh cluſtered ſpikes; the grain is alſo larger. There are two or three varieties of this differing only in the colour of the grain. It is frequently cultivated in Italy, (whence its trivial name) and other warm countries. [It is a native of both Indies, and of Cochinchina, and was cultivated by Mr. Miller in 1739. It flowers in july and auguſt [b].

Willdenow ſays that he has a variety from the Eaſt Indies with the rachis hirſute.

9. Height from two to four feet. Culm ſimple, erect, round, ſmooth, leafy. Leaves half a foot long, lanceolate, flat, entire, pubeſcent; ſheaths embracing the culm, villoſe at the neck. Spike terminating, compound, a foot long, compoſed of panicle-faſcicled racemes half an inch in length. Rachis flexuoſe, briſtly. Spikelets two to four, cluſtered, pedicelled, unequal, mixed with briſtles, green. Briſtles ſeveral times as long as the florets, from one to three inſerted into the baſe, flexuoſe, appearing hiſpid when magnified, ſerrate. Pedicels very ſhort, ſmooth. Inner valve of the calyx larger, ovate; acute, keeled. Corolline valves of the hermaphrodite equal, whitiſh: outer ovate, acute, ſomewhat keeled, concave; the other flat, included. Filaments very minute. Corolline valves of the male barren: outer larger ovate acute, concave; inner minute flat. Seed ovate, incloſed in the corolline glumes of the hermaphrodite. The ſmaller florets mixed with the others are commonly empty. It approaches near to *P. italicum*, but in that the ſpikelets are glomerate, on hirſute pedicels [c].

10. Culms ſimple, decumbent, leafy, rooting, long. Leaves naked, nerved, with very fine lines between the nerves, ciliate at the baſe. Sheaths tubercled and hairy. Spike compoſed of alternate ſpikelets an inch long. Flowers directed one way, alternately in pairs on a flexuoſe three-cornered rachis, one larger, both awned, ſometimes but ſeldom on the lower part of the ſpike ſolitary; all green. Outer valve of the calyx wide, ciliate at the baſe, with an awn three times as long as the floret, flexuoſe: inner almoſt of the ſame length, narrower, both compreſſed: inmoſt entirely concealing the corolla, longer, roundiſh. Nectary, a linear ſcalelet hairy at the top, within the calyx. Valves of the corolla equal, hyaline, acute; the outer involving the inner, and the inner involving the ſtamens and piſtil.

Native of the Eaſt Indies, whence it was ſent by Koenig.

11. Culms erect, three feet high, leafy. Leaves linear, flat, even, rough at the edge, with the mouths of the ſheaths hairy. Spike compound, half a foot long. Spikelets an inch and half in length; flowers in pairs and ſolitary, rather large. Outer valves of the calyx flattiſh, ovate-lanceolate, ending in a long rough-haired awn, three-nerved: inner of the ſame form and ſize, but more convex, awnleſs: acceſſory valve ſhorter by half and lanceolate: all of them hiſpid eſpecially at the edge. Outer floret male, compoſed of one flat lanceolate hyaline petal: inner female generally longer than the valves of the calyx, two-petalled; the petals cartilaginous, one flat, the other convex, embracing at the edge. Germ roundiſh-ovate, compreſſed.

Native of the Eaſt Indies, in ponds. Found by Koenig [d].

Willdenow thinks that *P. hiſpidum* of Forſter, found in New Caledonia, may be the ſame with this. Is P. hiſpidulum of Retzius. γ. 18. different from this?

12. Culm annual, two feet high, ſuberect, manifold, jointed, leafy. Leaves ſubereſt. Spikes commonly alternate, but ſometimes conjugate. Spikelets oblong, diſtich, ſpreading. Glumes awned, hiſpid. All the florets hermaphrodite. Rachis generally four-cornered [e].

Though Loureiro deſcribes it under the name of *Crus Corvi*, he obſerves that it is intermediate between that and *Crus Galli*, and different from both.

Linneus remarks, that it reſembles the next ſpecies very much, but that it is leſs and more tender. The panicle more nodding with a three-cornered (not five-cornered) rachis. The flowers on the ſpike are directed one way, and not incumbent all round on the rachis.

Native of the Eaſt Indies, Cochinchina and Japan.—Introduced in 1781, by Monſ. Thouin. It flowers in july and auguſt [f].

13. Root annual. Culms ſeveral, from one to two feet in height, thick, at firſt procumbent or oblique, but finally almoſt upright. Flowering-branches leafy, naked at top, even. Internodes three or four, the lowers ones divaricating. Joints thickened, cylindrical, duſky. Leaves on the culm very wide, flat, even on both ſides, hiſpid at the edges. Inſtead of a ligule, a ſhort triangular membrane, adnate, duſky. Sheaths looſe, compreſſed a little, cloven, even; the lower ones acute, leafleſs. General rachis linear, flattiſh, rugged, with one angle underneath, ſcarcely projecting, two at the ſides ſharper, and one above, with a groove for the inſertion of the branches. Spikes alternate, ſeldom conjugate, moſtly directed one way, ſubdivided, the terminating one more ſimple. Partial rachis three-cornered, ſomewhat flexuoſe, ſubdivided, involucred at the baſe with whitiſh hairs in bundles. Florets cluſtered, directed one way, on very ſhort ſubdivided peduncles, with bundles of hairs at the baſe, more apparently in the variety. Calyx nerved, pubeſcent, rugged; two of the valves mucronate, and the third flat and awned. Awn terminating, rugged, ſtraight, ſhort in α, but ten times as long as the glume in β. The third petal of the corolla membranaceous, flat, acuminate, between the flat valve of the calyx and the inner valve of the corolla [g].

Mr. Curtis remarks, that the leaves in more humble plants are three or four inches long, and from two to three lines in breadth; in taller plants ſix inches or nearly a foot in length, four lines and ſometimes ſix or ſeven broad, tapering to a point, keeled, ſmooth, the edges very finely toothed, and about the mouth of the ſheath hairy. Spikes pale green, ſometimes varying to purple. Spikelets often twelve in number, thick, roundiſh, the lowermoſt an inch and half in length, longer and farther aſunder than any of the reſt. Seed rather large, ſhining, covered by the valves of the corolla, round on one ſide, and flat on the other. Theſe ſeeds being large and plentiful, this graſs is much ſought after by ſmall birds.

Native of Virginia, the Cape of Good Hope, and ſeveral parts of Europe, as Sweden, Germany, Switzerland, the South of France, England. Thomas Williſell found it in a garden between Deptford and Greenwich; with a ſmooth ſpike, in a lane near the Neat-houſe gardens; with an awned ſpike, by the rivulet ſide near Peterſfield, Hampſhire, by Mr. Goodyer. Mr. Hudſon deſcribes it as growing by Martha's Chapel near Guildford. Dr. Milne found it in a coppice near Purfleet: and Mr. Curtis obſerved it in Batterſea field.

He has figured it without awns, in which ſtate it moſt frequently occurs with us. Leers remarks, that the florets are ſcarcely awned in cultivated grounds, but that in wet places it is found with very long awns. Linneus ſays that the latter, with awns ten times as long as the glumes, differs manifeſtly from the common ſort, in which the awns are ſcarcely half as long again as the glumes.

[a] Loureiro. [b] Hort. kew. [c] Swartz. [d] Retzius. [e] Loureiro. [f] Hort. kew. [g] Leers.

14. Culms filiform, branched, leafy. Leaves two inches long, ſubcordate at the baſe, with the edges of the ſheaths ciliate. Lower ſpikes remote, the upper ones often in whorls, ſhort. Flowers directed one way, in pairs, really ſeſſile, one of them placed higher than the other. Rachis depreſſed, with apparent teeth for the florets, furniſhed with a briſtle or two on each ſide of the floret. Calyx ovate, acute, with a ſhort acceſſory valve.—Native of China, whence it was ſent by Bladh.

Retzius is of opinion that P. repens of Burmann, *ind.* 26. *t.* 11. *f.* 1. is not the *repens* of Linneus, nor the *greſſorium*, but this ſpecies.

15. Root annual. Culms a ſpan high, round, aſcending. Leaves even, often ferruginous-ſpotted, purple at the throat without a ligule. Spike ſimple, directed one way, with a round weak rachis. Spikelets alternate, very many, ſubſeſſile, directed one way, ovate or ſomewhat oblong without any bundles of hairs. Florets ſomewhat ſtreaked. Anthers purple. Piſtils white, turning purple [4].

Native of the Eaſt Indies. Cultivated in 1699, by the Dutcheſs of Beaufort. It flowers in july and auguſt [5].

16. This is a very beautiful ſmooth even graſs. Culm compreſſed, leafy. Leaves linear. Rachis flat on the outſide, within or on the ſide of the ſpikelets keeled, margined. Spikes alternate, ſeſſile, almoſt upright, decreaſing, twice as long as the interſtices. Flowers directed one way, alternate, ſeſſile, imbricate. Calyx ovate, acute, with a ſmall rounded acceſſory valve.

It differs from *P. brizoides*, which it reſembles very much, in having the two valves of the calyx of the ſame length with the corolla, the acceſſory valve only ſhort and retuſe: both have the appearance of a *Paſpalum* [6].

Native of the Eaſt Indies, Arabia, and Madagaſcar.

17. Culms decumbent at the baſe, compreſſed, with purple joints. Leaves at the joints of the culm firſt ſingle, but afterwards ſeveral within the ſame ſheath, linear, even. Sheaths compreſſed, ſwelling, with the mouth ciliate and having a purple circle. Spike compound. Spikelets as many as twelve, linear, ſhorter than the interſtices, erect and almoſt preſſed cloſe, an inch long. General rachis three-cornered; partial linear, repand, ſomewhat rough, with a lengthened dagger-point. Flowers in two (not three) rows, compreſſed, awnleſs. Calycine valves two outer minute, retuſe, like ſcales; the third flat, the ſame ſize with the corolla, broad-ovate, acute, three-nerved. Corolla cartilaginous, with the valves flat and very ſmooth, one margin embracing. Stigmas pale roſe-colour. Nectary, two retuſe ſcalelets ſubvilloſe at the edge.—Native of the Eaſt Indies [7].

Swartz deſcribes a graſs of Jamaica under the ſame name, but it may be doubted whether it is the ſame ſpecies.—Culm from one to three feet high, ſimple, round, even. Leaves broadiſh, not long, acute, erect, rugged at the edge, ſtriated, ſheathing at the baſe; the neck beardleſs. Rachis terminating, almoſt a foot long, ſimple, linear. Spikes five or ſix, alternate, ſeſſile, preſſed to the rachis, directed one way: florets ſubſeſſile, approximating, in two rows on the ſame ſide, ovate, whitiſh. Two valves of the calyx equal, ovate, blunt, awnleſs; the third very ſmall, roundiſh. Valves of the corolla ſmaller, oblong. Stigmas purple. Seed faſtened to the corolla, roundiſh.

18. This is an upright graſs from two inches to half a foot in height. Root fibrous, the fibres undivided. Culms ſeveral, erect, cloathed with ſmooth leaves to the very loweſt ſpike. Rachis elongated. Spikelets from three to ſeven, ſhort, commonly ſix-flowered, erect, ſeſſile, preſſed cloſe, three quarters of an inch diſtant from each other. Flowers globular, alternate, directed one way, yellow, with green nerves. All the glumes of the calyx violet-coloured at the tip. It is very nearly allied to *P. brizoides*, which however is larger, green, and has longer leaves, with ſheaths relatively narrower. The ſpikelets have as far as thirteen ovate white unſpotted florets.——Native of Ceylon, whence it was ſent by Koenig.

19. Culm ten feet high, very finely ſtriated, aſcending. Leaves at the baſe of the culm diſtichally alternate, three inches long, on the middle of the culm one; all linear, blunt. Spike terminating, linear, three inches long, as it were halved. Rachis dilated, membranaceous, jointed, at the joints alternately deeply gaſhed, excavated alternately in front for the ſpikelets. Spikelets five-flowered, glued as it were in the hollow of the rachis, ſeſſile, with the partial rachis flexuoſe. Flowers awl-ſhaped, ſeſſile, ſtriated, flat in front, gibbous behind. Calyx three-valved, one-flowered: outer valve cartilaginous, flat, with the ſides bent at a right angle, lanceolate, ſtreaked: inner equal in length, thinner, boat-form gibbous, rounded and ſtriated at the back, ciliate-bearded at the tip, involving the edges of the outer valve: acceſſory valve ſhort, truncated, at the baſe of the outer valve. Corolla equal in length to the calyx, but narrower.—This is the *P. dimidiatum* of Linneus, very different from that graſs, which the younger Linneus made a ſpecies of *Rottbollia*.

Native of the Eaſt Indies, where it was found by Koenig.

20. This is very different from *P. birtellum* of Linneus. Culm decumbent, branched, villoſe and rooting at the baſe. Leaves lanceolate, with hairs thinly ſcattered over them; the ſheaths villoſe at the edge. Spikelets four or three. Rachis cloathed with long hairs eſpecially under the pedicels. Florets alternate, commonly abortive. The two outer calycine glumes equal terminated by a long awn: the third longer, acute, ſometimes awned; all villoſe. Corolla ſnow-white, very ſmooth.

Native of the Eaſt Indies, whence it was ſent by Koenig [8]: alſo of Italy.

21. Culm creeping, aſcending, three inches to a foot. The ſmaller leaves waved, the larger ſtiff. Spike compound. Rachis hirſute. Spikelets directed one way. Three valves of the calyx almoſt equal; the fourth, which is inmoſt, minute, membranaceous, awnleſs. The awns of the others long, (five times as long as the valve in the outmoſt) ferruginous-red, glutinous;—according to Linneus, filiform, blunt, finally hooked. Valves of the corolla awnleſs. Anthers whitiſh. Stigmas feathered, long, blood-red.—Native of the Weſt Indies [9].

This Graſs is cultivated, and thrives very luxuriantly, in all the low and marſhy lands of Jamaica, where it is almoſt univerſally uſed as fodder for all their ſtabled cattle: it is planted near the towns with great care, and found to be one of the moſt beneficial productions of the iſland. Its general growth is from two to four feet [10].

22. Culm three or four feet high, branched, compreſſed, even: joints villoſe, large. Leaves lanceolate, acute, even, rugged at the edge. Sheaths approximating, compreſſed, villoſe at the baſe. Peduncles from the ſheathing internodes, compreſſed, ſhort. Spikes rigid. Rachis linear, compreſſed, hairy: hairs long, thin, ſpreading. Spikelets pedicelled, alternate, ſharpiſh, ſomewhat compreſſed, ſtriated. Outer calycine valve minute; inner ovate, nerved, concave. Valves of the corolla ovate, very tender. Anthers purpliſh. Stigmas whitiſh. Seed oblong, compreſſed a little, ſmall. Glume of the neuter corolla two-valved: outer valve larger, concave, inner very minute, flat. Filaments none.

Native of Jamaica and other iſlands in the Weſt Indies, in woody mountainous paſtures.

23. Culm from two to three feet high, decumbent at the baſe, aſcending, ſubdivided at bottom, jointed, round, thick, pubeſcent. Leaves long, broad-lanceolate, rounded at the baſe, flat, villoſe, ſoft: ſheaths cloſely girting the culm, ſtriated, pubeſcent: joint thickiſh, villoſe. Spikes erect: ſpikelets two or three

[4] Linn. ſpec. [5] Hort. kew. [6] Retzius. [7] Idem. [8] Retzius. [9] Swartz. [10] Browne.

cluſtered,

cluſtered, on ſhort pedicels, turned towards the lower ſide, largiſh, oblong, brown. Outer valve of the calyx minute: inner ovate, blunt, ſtriated, pubeſcent. Valves of the corolla in the hermaphrodite florets nearly equal, ovate; one flatter. Anthers very dark purple. Stigmas the ſame and villoſe. Seed oblong, ſhining. Valves of the neuter corolla unequal: outer ovate, ſtriated, brown; inner flat, whitiſh, minute. Filaments none. It is known immediately from the other ſpecies by its ſoftneſs. The culms being thick and ſucculent, it is very grateful to cattle [a].

Swartz ſays that it is a native of Surinam, and is commonly called *Dutch-graſs* in Jamaica, where it grows in moiſtiſh fertile paſtures. He refers to a name in Browne, p. 133. which I do not find. Perhaps Dutch-graſs is miſtaken for Scotch-graſs; but why it has either of theſe names we are not told. See n. 21.

24. Height two or three feet. Culm jointed, erect, round, leafy, ſmooth. Leaves a foot long, rounded at the baſe, broad-lanceolate, acute, ſtreaked longitudinally, rough at the edge: ſheaths long, ſtriated, ſmooth, ſubvilloſe at the edge and neck. Spikes terminating, half a foot long, ſubverticillate. Rachis ſubflexuoſe, ſtiff, rough. Florets roundiſh or ovate, ſmall, brown: pedicels ſubbiflorous, the upper ones one-flowered, capillary, ſomewhat hirſute. Outer valve of the calyx one third of the ſize of the other: inner ovate, concave, marked with longitudinal lines, appearing netted when magnified, ferruginous-brown. Valves of the hermaphrodite corolla ovate, whitiſh; one ſmaller, included. Stigmas whitiſh. Male corolla empty: outer valve like the inner valve of the calyx; inner ſmaller, whitiſh, ovate.—Native of Jamaica in low graſſy places.

25. Roots long, filiform, ſtiff, perennial. Culm a foot high, very much branched, jointed, proſtrate, compreſſed a little, grooved, ſtiff, ſmooth. Branches from the ſheaths of the leaves, in bundles. Leaves rounded at the baſe, lanceolate, acuminate, two or three inches long, flat, entire, ſometimes waved at the edge, ſtriated a little, ſmooth: ſheaths longer than the leaves, wide, longitudinally open, ſtriated, pubeſcent, very much contracted at the edge and neck, ſubvilloſe: joints villoſe. Spikes on every ſide terminating the branches, commonly ſhorter than the leaves, an inch long, frequently concealed in the ſheaths. Spikelets pedicelled, diſtinct, ovate, acute, green and brown. Inner valve of the calyx ovate, acute, concave: outer three times leſs. Valves of the corolla ovate, obtuſe, whitiſh. Anthers whitiſh. Seed ovate incloſed in the glumes. Outer valve of the corolla in the male (or neuter) flower very like the inner valve of the calyx: inner ſmall, ovate, flat, more tender, whitiſh: theſe florets have no filaments.

Native of Carthagena in South America in graſſy places [b].

26. It is thus deſcribed by Linnæus, in his Mantiſſa, under the name of *P. indicum*. Culms filiform, proſtrate, very much branched, rooting. Leaves lanceolate, even, with the ſheaths ſhorter than half the internodes. Raceme terminating, peduncled, ſubſpiked, ſmall, ſhorter than the leaf, often eight-flowered, without hairs. Flowers alternate, ſometimes two in the ſame tooth of the lower raceme, ovate. Piſtils feathered, the ſize of the whole flower.

Retzius deſcribes it under the ſame name, as a filiform graſs, half a foot in height. Culm aſcending, naked above. Spikes ſcarcely half an inch in length, without any involucrets. Inner valves of the calyx ſlightly hiſpid, almoſt equal, boat-ſhaped, acute: acceſſory valve blunt, minute.—He can ſcarcely think it to be the *P. conglomeratum*, which ſeems to him to be the *Aira indica* of the Species: for in *P. indicum* the ſpike is not directed one way, nor are the florets blunt.

Native of the Eaſt Indies, by towns and in the ſtreets: ſent by Koenig.

27. This graſs is three feet high and ſmooth. Knots of the culm black. Sheaths ſmooth. Leaves long, linear, ſtriated, ſmooth. Spike a foot long, narrow. Flowers cluſtered. Peduncles one-flowered. Calyx two-flowered, two of the valves equal, acute, nerved, the acceſſory one leſs, obovate, obtuſe, membranaceous. It differs from all the ſpecies in the inflorescence.—Native of the Eaſt Indies, in ſtagnant waters [c].

28. Root annual. Culms leafy, even, with three joints, at the two lower procumbent, the upper oblique, very long. Flowering-branches from the joints. Leaves broadiſh, ſhort, ſublanceolate, even. Ligule crenulate. Sheaths ſomewhat compreſſed, blood-red, even, dotted: dots eminent, ſolitary and in cluſters, briſtle-bearing, ſcarcely viſible. Spikes three, four or five, linear, alternate, on very ſhort peduncles, inſerted into the culm, which between them is linear-three-cornered, flexuoſe, and by means of an axillary callus piliferous: when burſting from the ſheaths erect, parallel; when flowering horizontal, except the end one, which is erect. Rachis linear, ſubflexuoſe, flat, rugged, with a prominent nerve above, for the inſertion of the florets: which on the convex ſide are preſſed cloſe to the rachis, two together, or often three in each tooth: the loweſt peduncle ſhorter than the floret, the ſecond of the ſame length, the third, when there is a third floret, longer than it. Calyx awnleſs, pubeſcent: the leaſt valve triangular, three-nerved, but it is ſcarcely viſible with a magnifier, and is very frequently quite wanting: the ſecond, oppoſite to this, is blunt, embracing the third with its margin, ſubconvex, five-nerved: the third is flat, three-nerved, acute, ſometimes violet-coloured. Corolla leſs than the calyx. Stigmas purple. Seed rufous, ſhining [d].

The root forms ſmall tufts. Culms decumbent, curved at the joints below, and not unfrequently creeping, nine inches or a foot high, round, ſmooth, branching from the lower joints. Leaves acute, one or two inches long, two lines or a little more in width, waved chiefly at the edge, ſmooth as are alſo the ſheaths, glaucous or reddiſh green. Ligule blunt, more than half a line in breadth. Spikes three or four to ſeven in number, alternately and in a bundle from the top of the culm, from two to three inches long, and near one line in width. Scape (or rachis) compreſſed, waved all along at the edge. Spikelets ovate, acuminate or a little blunt, imbricate, ſmooth, compreſſed, purple above, green underneath, near a line in length and half a line in width, placed by pairs near each other, and covering the upper ſide of the rachis: one ſpikelet is ſeſſile, the other has a peduncle from half a line to a line in length. Calycine glumes of the ſame length and breadth with thoſe of the corolla, ovate, parting horizontally. Valves of the corolla opening alſo in width; the outer convex and cloſely embracing the inner one. Anthers purple. Styles white. Stigmas red and feathered. The ſeed falls with the corolla [e].

Pollich obſerved the larger variety figured by Buxbaum. The ſheaths and leaves of this are hirſute; the ſpikes and ſpikelets larger and greener.

Culms ſeveral, a ſpan or a foot in height, reddiſh, ſometimes branched, bending upwards, crooked, very ſlender and weak, generally four-jointed. Leaves from an inch to two inches in length, from two lines to two lines and a half in breadth, pointed, often waved on one ſide, having a few hairs on both ſides, the edges when magnified appearing very finely ſerrate: ſheath ſtriated, very hairy, the hairs proceeding from little prominent points. Spikes three, four or five, in gardens more, from an inch and half to four inches in length, filiform, all proceeding from the ſame point, or growing alternately, leaving a ſmall ſpace between them, dark purple or purple and green mixed. Spikelets growing one way, in pairs, preſſed to the rachis, pedicelled, ovate-lanceolate, pointed, purpliſh or green. Calyx three-valved, permanent; the loweſt valve very minute and ſhort, ſcarcely perceptible by the naked eye: the other two oppoſite, unequal, pointed, ribbed, rugged on the edges, the upper one the length of the corolla, which it enfolds with its margin; the lower one half the length of the upper. Valves of the corolla equal and ſmooth, the one receiving the other,

[a] Swartz defcr. [b] Idem. [c] Willdenow. [d] Loerr. [e] Pollich.

having

having a ſmall membrane at their baſe. Filaments very ſlender, a little longer than the corolla. Anthers ſmall, ſhort, purpliſh, forked at each end. Germ oblong. Styles filiform, the length of the ſtamens. Stigmas purple. Seed very ſmall, incloſed by the glumes of the calyx, as well as of the corolla [1].

I have given three deſcriptions diſtinct of this graſs, from three of our moſt accurate authors, two foreign and one domeſtic, becauſe it is ſuſpected that our *P. ſanguinale* is not the ſame with that of Linneus. Mr. Curtis is induced to conſider our plant as the *ſanguinale* of Linneus, rather by the figures and deſcriptions quoted by him, than by his ſpecific diſtinction, which does not well accord with our plant. The dotted ſheaths are not mentioned by Haller, Scheuchzer or Scopoli.—The knots within the baſe of the ſpikes, ſays Dr. Withering, and the dots on the leaf-ſheath, do not appear in Mr. Curtis's figure; but the latter are mentioned by Leers, and the former are expreſſed in his figure; ſo that there yet remains a doubt whether our plant may not be the *P. filiforme* figured by Jacquin, obſ. 3. t. 70.

It is obſerved by Miſs Jennings of this graſs, that all the ſtems which lie near the ground take root, and by this means, though an annual and ſhort-lived plant, it increaſes and ſpreads very wide [a].

Heiſter, Haller, Scopoli and Adanſon arrange this and ſome other ſpecies of *Panicum* under a diſtinct genus, which they call *Digitaria*, from the diſpoſition of the ſpikes, like the fingers of the hand ſpread out. But theſe having a three-leaved calyx, it ſeems better to continue them, with Linneus, Schreber, &c. under the genus *Panicum*.

This ſpecies is very univerſal, being found not only in Europe, but in Aſia and America; and the Society iſles in the Southern ocean: nevertheleſs it is not common in England. It grows at Elden in Suffolk, Witchingham in Norfolk, near Martha's chapel by Guildford, Wandſworth field, and in the gardener's grounds near Batterſea: flowering from july to ſeptember.

The name of *ſanguinale* is not taken from its colour, but from an idle trick which the boys in Germany have of pricking one another's noſtrils with the ſpikelets of this graſs, till they draw blood [b].

29. Culm creeping at the baſe, and above that upright, nine inches or a foot in height, glaucous, ſmooth, frequently branched from the lower joints. Leaves keeled, acuminate, ſtiffiſh, from one to four inches in length, one or two lines in breadth, hirſute on both ſides, ſomewhat rugged, glaucous. Ligule very ſhort, hairy. Sheath ſmooth with a yellow ſpot on each ſide at the inſertion of the leaf. Joints purple, ſmooth, ſometimes eight or nine. Spikes linear, four, five, or ſix, directed one way, three-ſided, ſlightly hairy at the baſe, proceeding in a bundle from the top of the the culm, at firſt purple, but by age acquiring the colour of chaff. Scape (or rachis) three-ſided and ſmooth: at each toothlet one ſeſſile ſpikelet, erect, ovate, acuminate, compreſſed, a line in length, and half a line in breadth, green and purple, ſmooth: the toothlets are about half a line from each other. The calyx embraces the corolla on its narrower ſide, and opens perpendicularly: the glumes are lanceolate, ſpread open above, and terminate in a very ſharp dagger-point; they are equal in length to the corolla, or one is a little ſhorter. The valves of the corolla ſeparate alſo perpendicularly; the larger of them is ovate, acuminate, keeled; the ſmaller narrow and acute, but nearly of the ſame length with the outer. Anthers purple. Styles and ſtigmas violet-coloured. The ſpikes curved archwiſe, are firſt erect, then vertical, and finally horizontal. Sometimes in the bundle of ſpikes a ſhort branch ſprings forth, on the top of which is another bundle of ſpikes few in number. The ſpikelets at firſt are preſſed cloſe to the ſcape; but in the time of flowering they recede in a vertical direction from it; and afterwards approximate to it again [c].

Root creeping widely through the looſe ſand, with ſtrong fibres at the knots. Culm rarely exceeding ſix inches in height. Leaf-ſheath parting from the culm when old, glaucous, hairy and pubeſcent throughout. Spikes four, diverging, dark purple changing to a cheſnut colour, near two inches long, not more hairy than the other parts of the plant. Florets all on one ſide of the ſpike-ſtalk, awnleſs [d].

There is ſome little doubt whether ours be the exact plant characteriſed by Linneus as the *P. Dactylon*. Cluſius's figure has long awns to the florets: but perhaps in the milder climates of Spain and Italy the plant may be awned, though not ſo with us. In the figures of Bauhin, Moriſon, Monti and Scheuchzer there are no awns, and therefore they agree better with our plant. The hairs mentioned in the ſpecific character, on the inſide the baſe of the ſpikes, are not ſo evident in our ſpecimens as to juſtify ſuch an application; for though our plants have ſome hairineſs there, they have it at leaſt as much on the outſide, and ſtill more in other parts [e].

Native of Europe, the Levant, and the Cape of Good Hope. Firſt found in England by Mr. Newton, between Penzance and Market-jeu in Cornwall; and lately again in the ſame place by Mr. Stackhouſe. It flowers in july and auguſt till late in the autumn.

30. Culms filiform, a foot high, aſcending, leafy, weak, putting out roots at the joints. Leaves ſmear-lanceolate, ſhort, naked. Rachis depreſſed. Florets directed one way, ovate, acute, generally in pairs and pedicelled unequally. Calyx ſtreaked with green, convex on one ſide, flat on the other, with a ſhort whitiſh acceſſory valve. Corolla of the ſame ſize and form with the calyx, not at all wrinkled. Stigmas blackiſh brown. Seed white, margined on the flatter ſide.

Native of the Eaſt Indies, in ſhady graſs ſpots. Sent by Koenig [f].

31. Leaves lanceolate. Culms almoſt leafleſs, a foot high, filiform, at top naked, upright. Spike filiform, thin, with a flexuoſe rachis, alternately on each ſide at the teeth. Florets two, one ſeſſile, the other pedicelled. Spikes ſlender, at firſt ſo cloſe as to appear one, although they are alternate.

Native of North America, where it was found by Kalm [g]. Alſo of Japan and the Cape of Good Hope, according to Thunberg; of the Society and Eaſter iſlands. Introduced in 1781, by Monſ. Thouin. It is an annual graſs; flowering from july to ſeptember [h].

32. It reſembles the preceding very much, but differs in having the culm and leaves hairy, the ſpikes a little thicker, but eſpecially in having the inner valve ovate, twice as large, and three-nerved. The acceſſory valve is extremely minute [i].

It is an annual graſs as well as the former. Culms from one to two feet high, covered with ſheaths that have long hairs cloſely ſet. Spikes long, linear, four or five. Rachis flat, membranaceous, flexuoſe. On one ſide of this the florets are fixed alternately in pairs, the pedicel of one being three times as long as that of the other [k].—Its native place is not aſcertained, notwithſtanding its trivial name.

33. Height a foot and half, branched at the baſe. Outer glume of the calyx ſmaller, lanceolate; inner larger, the length of the corolla, hairy at both edges: the acceſſory valve is a ſcalelet ſcarcely obſervable, and often wanting. Corolla quite ſmooth. Flowers lanceolate, acute, one of them ſeſſile. It varies with the leaves more or leſs hairy; and with the ſheaths and joints hairy and naked. This reſembles *P. filiforme* ſo much, that they may eaſily be confounded: and perhaps, *ſanguinale, filiforme, egyptiacum* and *ciliare* are nothing more than varieties.—In *egyptiacum* the acceſſory valve is a ſmall toothlet, and the outer valve of the calyx ſhort, ovate-lanceolate, and naked. In *filiforme* the acceſſory valve is ſcarcely larger, but the outer valve of the calyx is longer and lanceolate. In *ſanguinale* the acceſſory valve is as in *egyptiacum*, but the outer glume of the calyx is more ovate.

[1] Curtis. [a] Withering. [b] Curtis. [c] Pollich. [d] Stackhouſe in Withering. [e] Withering. [f] Retzius. [g] Linn. ſpec. [h] Hort. kew. [i] Retzius. [k] Willdenow.

This species was brought from Java and China by Wennerberg [a].

34. Culms prostrate, even, branched. Spikelets linear, straight, narrow. Flowers alternate below. Outer scale of the calyx shorter, spreading, adhering to the rachis [b].—Native of both Indies.

Retzius says he had it from Koenig, with the culms branching very much and leafy to the very spikes, with tender leaves: and from Thunberg, gathered at the Cape of Good Hope, with the culms creeping, less leafy at top, the leaves far more rigid, and the sheaths equitant in two rows. He doubts whether they are the same or different.

35. Root annual. Culms a foot high, upright or ascending, even. Leaves lanceolate, even, ciliate. Sheaths having hairs thinly scattered over them, inclosing the culms below. Peduncle long, terminated by four digitate racemes from one point, pointing one way, simple, loose, almost upright. Flowers alternate. The larger valve of the calyx ovate, three-nerved, acute, flattish, softly and denfely ciliate: the other valve lanceolate, shorter, naked. The outer petal has a ftraight terminating awn; the inner is narrower. The flower falls entire with the feed, and on account of the hairs in fome meafure refembles a bug [c].

Linnæus, not obferving the glume which is received by the margin of that which is awned, but taking the fmaller glume of the calyx for a glume of the corolla, made this grafs a *Millium*. Koenig, who found it in the Eaft Indies, firft difcovered it to be a *Panicum* [d].

36. Culms fomewhat branched, a foot high, narrower. Leaves fhort, rugged at the edge. Spikes two together, (according to Retzius commonly three, and fometimes four) terminating, nearly equal. Flowers feffile in a double longitudinal row along the rachis, awnlefs, ovate, even. Anthers yellow. Piftils feathered, purple.

It has the appearance of *Paspalum diftichum*, but the leaves are lanceolate and flat, not briftle-fhaped and involuted. Flowers fharpifh but not mucronate. The calyx has a fhort acceffory valve, whereas there is none in *Paspalum*. Flower ovate, convex, not compreffed. Peduncle pubefcent at top, not even [e].

Native of the Eaft Indies, where it was found by Koenig.

37. Culms proftrate, rooting, branched, leafy. Leaves fhort, clufered, tomentofe, as are alfo the fheaths. Peduncle elongated, erect, naked, terminated by two fpikes, diverging horizontally, directed one way, fquarrofe. Rachis membranaceous, dilated, flexuofe, jointed; at each joint a bundle of two or three flowers, fenced with involucres or difform cartilaginous bractes. One valve of the calyx very large, ovate, acuminate, flexuofe, the other fmaller, lanceolate; both hard and cartilaginous like the bractes: the acceffory valve fmall, acute, under the larger. Corolla lanceolate, the fize of the fmaller calycine glume. A bundle of barren flowers terminates the fpike. The appearance and ftructure are fo fingular, that it feems to conftitute a diftinct genus. It has fomewhat the appearance of a *Cenchrus* [f]. Linnæus placed it in that genus, and the defcription, from the *mantiffa*, has been already given under *Cenchrus muricatus*.

Willdenow remarks, that the fpikes are ufually in pairs, but that there is only one in Linnæus's own fpecimen.

Native of the Eaft Indies. Annual. Frequent in the fands of Malabar, during the rainy feafon.

38. This approaches neareft to *P. ftagninum*, but is very different. The culms and leaves are the fame as in that. Spikes compound, half a foot long, in clufters. Spikelets fcarcely an inch in length, almoft preffed to the rachis, binate, ternate or folitary. Outer valve of the calyx terminating in a naked awn four times as long as the flower: inner fomewhat longer terminated by a dagger-point or fhort awn; both hifpid efpecially at the edge: the acceffory valve fhort from a wide bafe furrounding the pedicel ending in a point, naked. Corolla as in *ftagninum*, but acuminate and hermaphrodite. Befides between the corolla and that valve of the calyx which has the longer awn, there is a hyaline petal, as in *P. ftagninum*; but in this there is no rudiment of ftamens or piftil.

Native of the Eaft Indies; fent by Koenig [g].

39. Culm creeping, leafy, rifing, filiform, tender, fimple. Leaves lanceolate, wider than in the reft, fhorter. Spikelets four or five, alternate, remote, preffed to the rachis, growing on one fide. Valves of the calyx lanceolate, flightly keeled, mucronate, with a ftraight awn, double the length of the florets, except the innoft, which has the awn fhorter.

Native of Ceylon [h]; and the Society iffes in the Southern ocean, according to Forfter.

40. This refembles the preceding very much. Culm upright, ftiff, fix feet high. Leaves long. Spike curved inwards. Rachis three-fided. Spikelets twelve or more, ovate-oblong, remote, alternate, feldom oppofite, on every fide of the rachis. Calyx fwelling a little, even, nerved; outer valve fhorter, ovate, acute; middle one with an awn; inner with a dagger-point fcarcely to be called an awn.—It is an annual grafs, native of Malabar [i].

41. In ftature this grafs emulates a fmall tree, fimple below and fafcicled above.—Native of Virginia [k].

42. Culms a foot high, erect, branched, even: with the internodes thickifh at the bafe and knee-jointed. Leaves with even fheaths, ftriated, ciliate at the edge and throat. Panicle with fimple, three-fided branches, channelled on one fide; at each tooth two or three flowers, with a hair or two on the pedicel. Outer valve of the calyx fhort, membranaceous, perfoliate; the others ovate.—Native of the Indies [l].

43. Native of the Cape of Good Hope. Found there by Thunberg.

44. Culms two feet high, very much branched, even, with the fheaths of the leaves hairy, and at length rugged. Panicle fpreading very wide, looſifh with filiform branches. Glumes one-flowered, awnlefs, ovate, green and purple, eight-grooved. Anthers faffron-coloured and piftils deep violet, by which it is readily diftinguifhed from *P. capillare* and others. Leaves even, linear, loofe, the margin towards the bafe toothletted with calluſes, fometimes furnifhed with a hair and fometimes without it. The outer valve of the calyx fhorter, wide, embracing.—It is an annual grafs, found by Forſkahl near Cairo [m].

Jacquin defcribes the root as perennial, compofed of thick long whitifh fibres. Culms annual, feveral, aggregate, thickening at the bafe into a fort of bulb and there connected and rooting, two feet high, erect, round, fmooth, not branched, as Linneus fays they are, but quite fimple without the leaft branchlet, only connate immediately above the root. Sheaths long, extending to the next knot above, hairy and rough, except the upper ones, which are often quite fmooth. Leaves enfiform-linear, about ten inches in length, four lines in width, acuminate, even, fmooth, fometimes thinly haired below, loofe, prominent underneath into a fharp midrib, fometimes flat, fometimes converging, cartilaginous-toothed at the edges, only to be difcerned by the magnifier. Panicle fpreading very much, filiform, branched, wide. Flowers fcattered, folitary, on capillary pedicels, which are commonly preffed fo clofe to the branchlets of the panicle, as not to be difcerned, fo that the flowers appear to be feffile. Calycine glumes one-flowered: the two inner valves awnlefs, ovate, blunt, eight-grooved, pale green with feven purple ſtreaks; the third outer valve fmall, acute, pale, not grooved. Corolla whitifh, pellucid, obtufe, nearly the fize of the calyx; the valves fubovate: one concave and marked with lines, the other flatter. Filaments white, purple at the tip. Anthers twin, oblong, yellow. Stigmas feathered, purple.

The feeds were fent from St. Domingo. It was introduced here as a native of Egypt in 1771, by Monſ. Richard, and flowers in July and auguſt [n].

[a] Retzius. [b] Linn. ſpec. [c] Linn. mant. [d] Retzius. [e] Linn. mant. [f] Retzius.

[g] Linn. [h] Linn. ſuppl. [i] Linn. ſpec. [k] Linn. mant. [l] Idem. [m] Hort. kew.

45. This is allied to the preceding. Culms creeping, a foot high, aſcending. Lower leaves wider, covering the ſtem all over with their ſheaths, ſpreading ſo much that they are almoſt divaricate and reflex, mucronate; the ſheaths ſubpubeſcent: the upper leaves are narrower, longer, erect. The panicle conſiſts of three or four erect racemes, ſcarcely branched, on which the flowers are alternate, ſomewhat remote, ovate. The outer calycine valve is very ſhort, and blunt.

It is an annual graſs, cultivated in the Eaſt Indies[a]. It was introduced in 1777, by Patrick Ruſſel, M. D. and flowers from July to September[b].

46. Culms upright, quite ſimple, leafy. Leaves ſpreading, with the ſheaths tomentoſe at the edge. Branches of the panicle few, naked, ſtiff, ſtraight half way, but the flowering part flexuoſe. Flowers for the moſt part in pairs, one of them pedicelled. The acceſſory valve of the calyx very ſhort and truncate. Corollas the length of the calyx, one hermaphrodite, the other male. Seed ovate, flattiſh. The whole graſs is whitiſh, and is taller than the other Panics.

Very common in Malabar, on the borders of ponds: found by Koenig.

47. Culms two feet high and more, ſlender, four-cornered-compreſſed, branching. Leaves linear, from four to ſix inches long, narrow, naked. Branches of the panicle capillary, remote, ſolitary, about eight in number. Florets alſo remote, moſt of them ſolitary, ſeſſile and pedicelled; but here and there in pairs, and then one is ſeſſile, and the other on a long pedicel; they are ovate and whitiſh. Pedicels three-ſided. Valves of the calyx almoſt equal, whitiſh ſtreaked with green; the acceſſory valve ovate. Seed white, ovate, flattiſh.—Koenig ſent it from Tranquebar.

48. Culm branched, creeping far and wide, putting out long and very ſimple fibres at the joints, thence riſing ſtraight, pubeſcent above the leaves. Leaves lanceolate, naked, ſhort. Sheaths ciliate, gaping between the joints. Panicle ſtiff and ſtraight, with few, almoſt upright branches, that are quite ſimple. Florets commonly in pairs, ſeldom in threes or ſolitary, ſeſſile. Involucres briſtle-ſhaped, varying in number, white. Outer valve of the calyx lanceolate, almoſt the length of the flower, terminated by a ſtraight awn three times its length; the ſecond ovate, half the length of the flower, with a very ſhort terminating awn; the third embracing the corolla, larger, wider, awnleſs: all green and ſtreaked. Corolla lanceolate, white, with equal valves.—Wennerberg brought it from China[c].]

49. Common Millet riſes with a reed-like channelled ſtalk, from three to four feet high: at every joint there is one reed-like leaf, joined on the top of the ſheath, which embraces and covers that joint of the ſtalk below the leaf, and is cloathed with ſoft hairs; the leaf has none, but has ſeveral ſmall longitudinal furrows running parallel to the midrib. The ſtalk is terminated by a large looſe panicle, hanging on one ſide.

[Loureiro deſcribes the culm as annual, three feet high, upright, thick, ſomewhat compreſſed and flexuoſe, hollow, jointed, branched. Leaves awl-ſhaped, largiſh, hairy, flat, reflex. Panicles ſcattered, large. Calyx three-valved, the outer glume only half the ſize. Corolla three-valved; glumes membranaceous, ſharpiſh; outer one-third of the ſize, bifid at top. Styles capillary: ſtigmas ovate, feathered, coloured. Seed ſubovate, compreſſed a little, pale, ſhining.

Native of the Eaſt Indies, and China. In thoſe countries, as alſo in the South of Europe, it is cultivated as an eſculent grain. It varies in the colour of the ſeed.]

Mr. Miller mentions two varieties, one with white, the other with black ſeeds, but not differing in any other particular. He has alſo another ſpecies, which he names *Milium ſparſum*. It was found at La Vera Cruz by Houſtoun, who called it *M. panicula ampla erecta ſparſa*. It has a more ſlender ſtalk than common Millet, about three feet high. The ſheaths have no hairs but are channelled. The leaves are ſhorter. The panicle ſtands erect, and the chaff has ſhorter awns or beards.

[Loureiro mentions a variety with browniſh or duſky red ſeeds. Retzius deſcribes the variety with black ſeeds (Milium ſemine nigro. *Bauh. pin.* 26. & *Mor. hiſt.* 3. 196. *f.* 8. *t.* 5. *f.* 2.) Culm round, jointed almoſt upright, branched. Leaves a foot long, half an inch wide, hairy, with hiſpid ſheaths: no ligule, but inſtead of it widiſh briſtles. Panicle nodding, with the peduncles commonly in pairs, dichotomous, rugged backwards, flexuoſe. Flowers on each pedicel commonly two, ſometimes one or three, pedicelled, ſometimes but very ſeldom one ſeſſile. Calycine glumes ovate, acute, nerved; the third glume is much ſhorter. Corolla globular, hyaline. Seed browniſh-black.

Variety β. has the panicle attenuated, the culm upright, the leaves lanceolate, the ſheaths even and ſmooth[e].

Gerarde, in his Herball (A° 1597.) ſays, "I have of it yearly in my garden."

50. Root perennial, ſtoloniferous. Culms eight feet high and more, erect, branching very much. Leaves rough at the edge, and on the larger nerves, but leſs ſo. Edges of the ſheaths bearded with bundles of whitiſh hairs like fringes. Panicle a foot long, branching very much. Pedicels two-flowered, ſo that one flower is ſubſeſſile on the pedicel of the other. Florets copious, green, round, acuminate. Calycine valves acute, even the acceſſory one, which is one-third ſhorter. Hermaphrodite floret two-petalled: the male one ſeems one-petalled.

Cultivated in Malabar, where it never produced ſeed, but is increaſed by offſets or runners; whence Koenig ſuppoſes it not to be a native, but to have been introduced from ſome other parts.

The natives there uſe it, particularly in ulcers of the noſe, and as a diſcutient in other caſes, either ſimply bruiſed, or made into a cataplaſm by boiling, as Koenig reports.

51. This is a tall graſs, with a ſlender culm and black knots. Leaves acuminate, very ſlightly hairy, five inches long, and three quarters of an inch wide. Sheaths ſhorter than the joints (or internodes with the edges bearded. Panicle almoſt a foot long, with long branches ſpreading at an acute angle and rugged, ſpotted with black in the axils. Flowers ſcattered, ſolitary or in pairs, pedicelled, oblong, acute, ſmall. The two inner glumes of the calyx equal, purple; the acceſſory valve a little ſhorter, whitiſh; all lanceolate. Corolla of the ſame length and ſhape with the calyx.—Wennerberg gathered it in Sumatra.

52. Height a foot and a half. Culm filiform, decumbent at the baſe, rooting here and there. Leaves ſhort, perfectly lanceolate, with white ſcattered hairs. Panicle with ſhort ſolitary ſubdivided branches, ſpreading at an acute angle. Flowers ſmall, ſeſſile and pedicelled, oblique. The hollow glume of the calyx ſhorter, almoſt boat-ſhaped; the flattiſh one longer; both rugged-muricate: the acceſſory one ſmall, lanceolate, ſtriated, placed under the preceding. Corolla oblique, very ſmooth.—Native of the Eaſt Indies; ſent by Koenig[f].

53. This graſs reſembles *Poa capillaris*, but is entirely hirſute[g]. It is three feet high, with a panicle more than a foot long, the peduncles and pedicels ſtiff and ſtraight. Calyxes pale green, narrow, naked. Joint of the ſtem bearded, but the beard turned upwards. Sheaths of the leaves ſtriated, and between the ſtreaks callous dots with hairs on them. There are alſo hairs on the leaves themſelves ariſing from raiſed dots[h].

Native of Virginia and Jamaica. Cultivated in 1758, by Mr. Miller. It is an annual graſs and flowers from June to auguſt[i].

54. This has been confounded with the preceding. It is about a foot in height. Culms decumbent, branched, ſlightly hairy. Leaves two inches long,

[a] Linn. ſpec. [b] Hort. kew. [c] Retzius. [d] Willdenow from Moench. [e] Retzius. [f] Linn. ſpec. [g] Retzius. [h] Hort. kew.

narrow,

narrow, hairy as are alſo the ſheaths, but they have no callous dots. Beard of the joints denſe, turned downwards. Panicle ſcarcely three inches long, the whole of an ovate form, with the pedicels remarkably flexuoſe. Calyxes ovate, blunt, with a few rough hairs'.—Native of the Eaſt Indies.

β. Retzius mentions a variety that is wholly ſmooth, found by Koenig every where in the rice fields.

55. Culm ſimple or branched, two feet high and more. Leaves enſiform with ciliate ſheaths. Panicle ſpreading, compound. Peduncles capillary, flexuoſe, ſmooth. From each tooth of the rachis two florets, one ſubſeſſile, the other pedicelled.—Native of Jamaica and Japan*.

56. This is very nearly allied to *P. greſſarium*. Root creeping, perennial. Culms from five to ten feet high, upright, ſimple, even. Leaves lanceolate, towards the top convolute and ſharp, ſmooth, except at the edge, which is rugged, and at the baſe, which is rough-haired. Panicle erect, a foot long and more: the lower branches in whorls, the upper in pairs. Florets numerous, alternate, ovate-ſharpiſh, preſſed to the raceme, on ſhort ſubflexuoſe pedicels. Spikelets polygamous. Outer valve of the calyx very ſmall: inner oblong, ſharpiſh, pale. Inſtead of the hermaphrodite there is often a female floret with a male at the ſide of it, or a female alone without the hermaphrodite and male. Seed oblong, ſhining.

Native of the Weſt Indies; ſaid to have been brought from the coaſt of Africa. Guinea-graſs is much eſteemed in Jamaica both for ſheep and cattle, and flowers chiefly in october'.

57. Height from one to two feet. Roots and radicles very long, filiform. Culm creeping at the baſe, aſcending, ſomewhat branched, rooting at the joints, round, ſtriated, pubeſcent or ſmooth, looſe. Branches from the ſheaths of the leaves, ſomewhat hirſute. Leaves diſtich, obliquely elliptic at the baſe, unequal on the ſides, terminated by a lanceolate point, quite entire, ſomewhat waved, very thin and very finely ſtreaked, ſmooth underneath, hairy above. Sheaths at the joints ſhort, open in front, ſtriated, hirſute, hairy at the neck. Knots rather large, villoſe with white hairs. Panicles ſmall, erect, with terminating and axillary peduncles; branches ſhort, few-flowered: florets pedicelled, ſmall, green. The two valves of the calyx are oblong, nearly equal, awned at the tip. The two valves of the corolla, in the hermaphrodite flower, are oblong, blunt, whitiſh; one of them ſmaller and included. Anthers pale. Styles rather long. Stigmas feathered, whitiſh. In the male flower, the outer valve is ovate, acute, concave, and includes the inner, which is ſmaller, ovate, acute and more tender. Anthers purple.—Native of Jamaica and Hiſpaniola.

58. This graſs is a ſpan in height. Culm creeping, but in a fertile ſoil erect, round, tomentoſe: branchlets aſcending, ſhort, about an inch in length, leafy, theathed, jointed, tomentoſe-hirſute. Leaves half-embracing, ſhort, broad-lanceolate, entire, acuminate, flat, extremely hirſute at the edge, ſoft. Sheaths ſmall, rough-haired, with the ligule hirſute. Panicles ſmall, very ſhort: racemelets ſimple: florets ſmall, ovate, obtuſe, on ſhort waved pedicels. Inner calycine valve ovate, concave, ſtriated, rough-haired; outer minute. Valves of the hermaphrodite corolla ovate: filaments the length of the glumes; anthers purple: ſtigmas villoſe, dark purple, ſhort: ſeed oblong, ſhining. In the male or neuter floret, the outer valve is like the inner calycine valve, ovate, ſtriated; the inner is very ſmall, flat, whitiſh.—Native of Jamaica, on ſandy fields in the mountains.

59. Culm a foot high and more, decumbent, creeping a little, branched, jointed, ſheathed, round, ſtriated, ſmooth. Sheaths at the baſe of the branches elongated, embracing, ſtriated, ſmooth: branchlets aſcending, filiform, ſtrict, ſubdivided, ſheathed, leafy, round. Leaves half embracing, lanceolate, broadiſh, an inch long, acuminate, rigid, ſtriated, ſomewhat rugged to the touch. Panicle ſmall, oblong; compoſed of racemelets which are alternate, diſtant, ſubdivided, capillary, ſhort, rugged. Florets remote, ovate, minute. Valves of the calyx almoſt equal, ovate, obtuſe, concave, rigid, ſtreaked with purple. Glumes of the corolla, in the hermaphrodite florets, a little leſs than thoſe of the calyx, more ſlender, whitiſh. Filaments ſhort. Anthers ovate, largiſh, bifid, vertical, whitiſh-yellow. Styles longer than the glumes. Stigmas villoſe, long, recurved, whitiſh. Seed roundiſh, ſhining, very minute. In the neuter floret, the outer valve of the corolla is ovate and ſtriated, the ſame ſize with the inner glume of the calyx: the inner valve is tender, leſs, whitiſh. This graſs is diſtinguiſhed by its rigidity.

Native of Jamaica in the high mountains, with *Aplusia Zeugites*.

60. Height from one to two feet. Culm jointed, round, pubeſcent. Leaves retuſe and oblique at the baſe, entire, ſmooth, ſtriated, three or four inches long. Sheaths long, with a contracted ligule, appearing ſomewhat hirſute when magnified. Panicles peduncled, an inch and more in length; peduncle long, filiform: florets browniſh green, ovate. Pedicels now and then two-flowered. Outer valve of the calyx leſs, inner ovate. The reſt as in *P. carthaginenſe*, which it reſembles: but the culm is by no means branched, the ſheaths are more contracted, the panicles peduncled, the florets in pairs, and the glumes ovate not acute.—Native of Jamaica in boggy paſtures.

61. Height from two to four feet. Culm ſubdivided, compreſſed a little, ſtriated, even. Leaves ſtriated, even, ſpreading. Sheaths cloſe, even. Branches of the panicle ſubdivided, ſpreading, almoſt upright, flexuoſe. Florets very minute, pedicelled, preſſed cloſe, approximating, ovate, bright green. Outer valve of the calyx leſs by half; inner a little larger; all ovate acute concave ſtriated, bluntly keeled at the edge, appearing ciliate when magnified. Valves of the corolla in the hermaphrodite floret equal, leſs than the calycine glumes, ovate, concave. Filaments very ſhort. Anthers yellowiſh. Stigmas blood-red. Seed roundiſh, ſhining, extremely ſmall. In the neuter floret, the outer valve reſembles that of the calyx.

Native of Jamaica, in dry woods; flowering at the end of the year*.

62. Leaves as wide as thoſe of *Commelina*, embracing at the throat, villoſe on the outſide of the neck about the throat, and hairy alſo on the edge of the leaves at the baſe. Panicle of a very middling ſize, compoſed of lateral racemes, not ſubdivided, but producing ſimple pedicels. Florets awnleſs, largiſh.—Native of North America'.

Loureiro ſays that he found it in Cochinchina. He deſcribes the culm as annual, thick, five feet high. Leaves lanceolate, large, plaited and grooved, with an embracing villoſe neck. Florets awnleſs, in a panicle that is ſomewhat contracted or ſqueezed, with the lateral branches moſtly ſimple. Seed pale.—Introduced 1765, by Mr. John Cree. It flowers in auguſt and ſeptember; and is a perennial graſs'.

63. Height three or four feet. Culm ſimple, erect, round, at top compreſſed and pubeſcent. Leaves long, wide, flat, entire, ſtriated, ſpreading, even. Sheaths cloſe, ſomewhat rough-haired. Branches of the panicle ſimple, alternate, ſpreading; the loweſt ſomewhat compreſſed, even. Florets preſſed to the rachis, ovate, blunt, ſmooth, yellow. Pedicels equal. Outer valve of the calyx only one-third of the ſize of the inner one; both ovate, obtuſe, concave, ſtriated, pellucid. Valves of the hermaphrodite corolla ovate, concave. Filaments ſhort. Anthers ſmall, purple. Stigmas villoſe, blood-red. Seed oblong, ſhining, yellow. Outer valve of the neuter floret concave, ovate, ſtriated: inner flat, more tender, whitiſh.

This ſpecies is ſingular in the colour being conſtantly yellow, which is not the caſe in the reſt. It occurs, but rarely, in dry places, in the Southern parts of Jamaica.

64. Culm a foot, ſometimes two feet in height, aſcending, filiform, round, leafy, ſmooth. Leaves long, ſharp, erect, ſtriated, even. Sheaths ſtriated,

villoſe

* Thunberg. ' Swartz. * Swartz, ' Linn. ſpec. ' Hort. kew.

villose at the neck and throat. Knots purple. Branches of the panicle alternate, flexuose, somewhat rigid. Florets rather distant, pedicelled, ovate, acute, smooth. Calycine valves ovate, acute, smooth; outer less by half than the other. Glumes of the hermaphrodite corolla equal, less than the calyx, pellucid, whitish. Anthers purple. Stigmas villose, blood-red. Seeds roundish, yellow, shining. In the male floret, outer valve ovate, acute, smooth: inner minute, flat, whitish. Filaments one to three, minute, barren.—Common in dry places in the West Indies.

This species bears much resemblance to *P. repens*; but that has a more rigid habit, and creeping culms: the leaves spreading, somewhat divaricating, wider, much striated, rather rugged at the edge, with the sheaths subdistich, almost covering the culm: panicle more subdivided, with the florets blunter and pale.

65. Culm three or four feet high, round, leafy, smooth. Leaves a span long, entire, longitudinally striated, smooth. Sheaths more contracted. Panicle a foot long: branches alternate, stiffer, angular, subflexuose, smooth. Spikelets large, smooth, pedicelled, commonly in pairs, one shorter than the other. Outer valve of the calyx larger but shorter, wide, acute, slightly keeled: inner a little longer, ovate, keeled, striated. Corolla pale: outer valve ovate, acute, including the inner, which is smaller and flattish. Anthers pale, seeming to be barren. Style bifid. Stigmas longer, pale purple. Outer valve of the male corollet larger, acute, green; inner a little less, ovate, acute, whitish. Anthers purple. Seed in the hermaphrodite floret included in the valves, which are hardened, yellow and shining. It is distinguished by the spikelets being much larger than in any of the species.

Native of Jamaica, in mountain woods, in the Southern parts [a].

66. Culms dichotomous, branched. Leaves ovate-lanceolate, with the sheaths dotted and hairy; the racemes of fructification are so entirely concealed within them, that no vestige appears on the outside: in other respects it is nearly allied to *P. latifolium*.

Native of Pensylvania, where it was found by Kalm.

67. This grass contends for height with the loftiest trees in the East Indies, where it is a native; and yet the culm is scarcely wider than a goose quill [b].

In Linneus's *Flora zeylanica* it is said to be creeping. Leaves embracing, even, wider in this grass, in proportion to its length, than in any other: hence the culm resembles that of *Commelina*. Sheaths narrow, striated. Stem at bottom often branched. Panicle less wide, with very slender and almost capillary peduncles. Florets small, awnless.

Introduced in 1776 by Monf. Thouin. It flowers here in march and april [c].

68. Culms filiform, even. Leaves lanceolate, even, five-nerved underneath, rugged at the edge; with the sheaths deeply striated. Panicle erect, narrow, with the branches subramose. Flowering calyxes subsubulate, curved on the outside, striated, awnless, the outer valve under the curvature membranaceous, cordate, acute, extremely small. Fruiting calyxes three times larger, oval, gibbous, very blunt, many-grooved, purple. Corolla shorter by half than the calyx, membranaceous.—Native of the East Indies.

69. This is a very tall grass, with a very large diffused panicle [d].—Native of Virginia, and other parts of North America. Introduced in 1781, by Mr. William Curtis. It flowers in auguſt and ſeptember [e].

70. Native of the East Indies. This, or one like it, is also found in Portugal [f].

71. Culms a span high, procumbent, leafy, rooting. Leaves smooth, narrow. Panicle small, strict, with the peduncles sometimes a little flexuose. Calycine glumes very blunt, unequal.—Native of the East Indies: found by Koenig [g].

72. Culm from one to two feet high, round, leafy, subdivided at the joints, grooved, striated. Knots larger, approximating, brown. Leaves oblique at the base, acuminate, slightly keeled, entire, longitudinally striated, smooth. Sheaths rather large, often ventricose, striated. Peduncles from the upper sheaths, filiform, long, very loose. Branches of the panicle clustered in form of a thyrse. Spikelets pedicelled, approximating, erect, pale green, smaller. Inner valve of the calyx ovate-lanceolate, acuminate: outer three times smaller, ovate, acute. Valves of the corolla in the hermaphrodite florets minute, ovate, shining, whitish, hardish, one a little less, the other included. Filaments very minute. Anthers purple. Style bifid. Stigmas purple. Seed oblong, whitish, shining. In the male or neuter floret, the valves of the corolla almost equal, lanceolate: outer greener; inner more tender involved in the outer.——Native of Jamaica, among other grass in woods.

73. Culm a fathom in height at most, round, pubescent. Branches divaricating, leafy, hirsute. Leaves acuminate, half a foot long, spreading, striated, sanguinose-hirsute, soft. Sheaths open in front, very hirsute. Knots larger. Panicles half a foot long; with spreading, flexuose, smooth branches. Spikelets smooth, larger, remote, on capillary pedicels. Outer valve of the calyx less by half, ovate, obtuse, villose at top: inner larger, ovate, striated, concave, slightly keeled, villose at top. Valves of the corolla in the hermaphrodite floret ovate, paler. Anthers purple. Seed inclosed by the yellow indurated valves of the corolla, ovate on one side, flat on the other. In the corolla of the male or neuter floret, the outer valve is larger, concave, ovate, acute, smooth, keeled: inner flat, less, more tender.—Native of Jamaica.

74. Culm a fathom in height, erect, round, leafy, smooth. Leaves ovate at the base, erect, longitudinally nerved, striated, smooth. Sheaths close, with the neck contracted and villose, striated, long. Knots small, with a black ring. Panicle erect, dense, branched; branches and branchlets capillary, strict. Spikelets small, numerous, pedicelled, pale green. Valves of the calyx almost equal, convex, ovate, striated, green: outer ciliate at top, even when ripe villose; the other smooth. Valves of the corolla in the hermaphrodite floret ovate, yellow, shining. Anthers whitish. Stigmas very minute, villose, whitish. Seed white, shining: in the male, valves less, ovate, yellow, one less than the other. Filaments two or three, with very minute anthers.

Native of Jamaica, in the high mountains near Coldſpring in St. Andrew's parish.

75. Culm three or four feet high, smooth, leafy. Leaves broad-lanceolate, an inch in breadth, more than a foot in length, acuminate, erect, rounded at the base, hairy, ciliate at the edge, marked with lines, smooth, somewhat rugged underneath. Sheaths long, close, smooth, contracted at the neck. Ligule villose. Panicle almost a foot long, erect. Branches in a sort of whorl, scattered, villose at the base, spreading, subdivided, somewhat rigid; the last capillary. Spikelets roundish, larger, shining, on flexuose, capillary pedicels. Valves of the calyx equal, ovate, blunt, smooth, glutinous. Valves of the corolla in the hermaphrodite floret smaller, whitish. Filaments capillary, whitish. Anthers purple. Stigmas hairy, purple. Seed roundish, hardish, white, shining. Outer valve of the corolla, in the neuter floret, ovate, obtuse, smooth: inner smaller and more tender.

Native of Jamaica, in the Southern parts, in the woods of the highest mountains. It is there called *Ginger-graſs*, on account of the width of the leaves. The great clamminess of the spikelets, whence its trivial name, is peculiar to this species [h].

76. This grass is a foot high, slender, smooth. Culm leafy up to the panicle, decumbent, putting forth long very simple, solitary rooting fibres at the joints. Leaves linear-lanceolate, acute, an inch and half in length, having long white hairs at the base on both edges. Panicle two inches long, slender, upright. Flowets small, pedunculed, oblique, blunt, purple, naked. Accessory valve of the calyx acute, half the length of the flatter valve. It resembles *P.*

[a] Swartz. [b] Linn. spec. [c] Hort. kew. [d] Linn. syst. [e] Hort. kew. [f] Linn. spec. [g] Retzius. [h] Swartz.

trigonum,

trigonum, even in the ſhape of the ſeed.—Gathered near Canton in China, by Wennerberg[a].

77. Culm one foot high to two feet, ſometimes rooting, ſubdivided at the baſe, looſe, round, ſmooth, leafy: knots approximating, ſmooth. Leaves acute, rounded and oblique at the baſe, entire, ſpreading, ſtriated. Sheaths cloſe, longitudinally ſtriated, ciliate. Ligule open, hairy. Panicles erect, often from the boſom of the upper leaf, as from a ſpathe. Branches in alternate cluſters, multifariouſly ſubdivided, ſpreading very much, ſo fine that the extreme ones are ſcarcely viſible. Spikelets diſtinct, pedicelled, very minute, oblong, green. Outer valve of the calyx very ſmall; inner ovate, ſcarcely ſharp, ſtriated a little. Valves of the corolla, in the hermaphrodite floret, equal, ovate. Anthers whitiſh. Stigmas feathered, pale. Seed oblong, ſhining, very minute. Outer valve of the corolla, in the male or neuter floret ovate acute; inner minute, flat, whitiſh.

On comparing ſeveral ſpecimens of *Pan. breviſolium*, from the Eaſt Indies, with the Jamaica graſs, they do not appear to be diſtinct, although the latter is larger and more ſpreading, and with the glumes ſcarcely blunter. Calyxes in both two-flowered, and the leaves wider or narrower. Some other ſpecies have ſhort leaves, and therefore Linnæus's trivial name of *breviſolium* is a bad one: *trichoides* is very deſcriptive of the panicle in this ſpecies.

Milium capillare of Rottboell. *act. hafn.* 1778. 271. which is Pan. capillare of Rolander, ſeems to be only a variety of this, the third calycine glume, of which thoſe two authors deny the exiſtence, is found in many of the ſpikelets, though extremely ſlender. All the parts are larger in this variety, except the ſpikelets, which are very ſmall; the ſheaths are very ſmooth, but the leaves are pubeſcent[b].

Dr. Patrick Browne calls it *Smaller Wood-graſs*, and ſays it is very common in the woods of Jamaica, agreeing for the moſt part with the Guinea graſs both in the arrangement and formation of its flowers. The ſtalk and leaves are excellent fodder for all ſorts of cattle, and the ſeeds ſerve to feed ſmall birds.

78. Native of Jamaica.

79. Culm four or five feet in height, ſimple, round, leafy. Leaves broadiſh, two feet long, erect. Sheaths cloſe, grooved-ſtriated. Panicle a foot long, erect. Branches in whorls, capillary, ſpreading, appearing rough in the magnifier. Spikelets pedicelled, ſomewhat remote, ſmall, pale green. Valves of the calyx ovate, acuminate, concave, ſtriated: outer leſs by half. Valves of the corolla in the hermaphrodite floret ovate, acute, whiter. Anthers purple. Stigmas feathered, whitiſh: in the neuter, outer valve of the corolla like the inner of the calyx; inner more tender, whitiſh. It is very nearly allied to P. maximum (n. 56.) differing chiefly in its ſhagginess[c].

Swartz has another ſpecies from Jamaica, which he names *Pan. ceſpitoſum*, very nearly allied to *groſſarium* (n. 55.): but that has the culm more erect, large and ſtrict. The ſpikes panicled, more numerous and approximating; with cluſtered, larger ſpikelets.

Thunberg alſo has a ſpecies from the Cape of Good Hope, not enumerated above—*Panicum caudatum*, which he thus characteriſes: Panicle ſubſpiked contracted or ſqueezed cloſe, flowers ſolitary, glumes ſmooth, acute.

We are obliged to Retzius and Swartz for the greater part of the above ſpecies, which are natives either of the Eaſt or Weſt Indies. The former has, in his ſecond faſciculus, a ſpecies, which he names *Pan. Caffrorum*. It is called *Caffer-korn* at the Cape, and may be of the genus *Holcus*.

In his fifth faſciculus, *p.* 18. *n.* 34. he has *Pan. biſpiculum*, ſent by Koenig from the Eaſt Indies, which he ſays is very nearly allied to *Pan. flagellatum*, but is very different from it. The corolla is acuminate and hermaphrodite. Between the corolla and the long-awned valve of the calyx there is a hyaline petal, as in that; but in this there are no ſtamens, nor is there any rudiment of a piſtil.]

[a] Retzius. [b] Swartz. [c] Idem.

PROPAGATION AND CULTURE.

7, 8. The ſeeds of theſe ſorts may be ſown in the ſpring, at the ſame time as Barley is ſown, and may be managed exactly in the ſame way; but they ſhould not be ſown too thick, for theſe ſeeds are very ſmall, and the plants grow ſtronger, therefore require more room.

The German ſort does not grow above three feet high, unleſs it is ſown on very rich land, in which caſe it will riſe to be four feet high; but the leaves and ſtems of this Corn are very large, ſo require to ſtand four or five inches apart, otherwiſe they will grow up weak and come to little. Theſe large growing Corns ſhould be ſown in drills at about eighteen inches apart, ſo that the ground may be hoed between the rows, to keep them clear from weeds, and the ſtirring of the ground will greatly improve the Corn. In auguſt the Corn will ripen, when it may be cut down and dried, and then ſhould be houſed.

The Italian Panic grows much larger than the German, and produces much larger ſpikes; ſo this ſhould be allowed more room to grow, otherwiſe it will come to little. This is alſo later before it ripens, ſo it is not very proper for cold countries.

Moſt of the other ſorts are natives of very warm countries, where ſome are uſed by the inhabitants to make bread. Theſe grow very large, and require a good ſummer, otherwiſe they will not ripen in this country. The ſeeds ſhould be ſown the latter end of march or the beginning of april, on a moderate hot-bed, and the plants ſhould be planted out when grown to a proper ſize, upon a bed of light rich earth, in a warm ſituation. They ſhould be planted in rows about three feet aſunder, and the plants muſt be kept clear from weeds. When the plants are grown pretty tall, they ſhould be ſupported by ſtakes, otherwiſe the winds will break them down; and when the Corn begins to ripen, the birds muſt be kept from it, otherwiſe they will ſoon deſtroy it. Theſe are preſerved in ſome curious gardens for the ſake of variety, but they are not worth cultivating for uſe in England.

49. The common Millet was originally brought from the Eaſtern countries, where it is ſtill greatly cultivated, from whence we are furniſhed annually with this grain, which is by many perſons greatly eſteemed for puddings, &c. but is ſeldom cultivated in England in quantity, but by way of curioſity in ſmall gardens, for feeding of poultry; but the ſeeds generally ripen very well.

They muſt be ſown the beginning of april, upon a warm dry ſoil, but not too thick, becauſe theſe plants diviſe into ſeveral branches, and ſhould have much room; and when they come up, they ſhould be cleared from weeds, after which they will, in a ſhort time, get the better of them, and prevent their future growth. In auguſt theſe ſeeds will ripen, when it muſt be cut down, and beaten out, as is practiſed for other grain; but when it begins to ripen, if it be not protected from birds, they will ſoon devour it.

[21. Scotch-graſs is propagated in Jamaica by the joints or root, and ſet in ſmall drilled holes about two feet and a half aſunder. The young ſhoots begin to appear in a few days, and as they grow, they ſpread and creep along the ground, caſting a few roots, and throwing out freſh ſhoots from every joint, as they run; theſe ſoon ſupply the land, and fill the field with ſtanding plants, which alone are generally cut. It is fit to cut in ſix months from the firſt planting, and every month or ſix weeks after, if the ſeaſon fall in kindly, and due care be taken to keep the ground free from weeds. An acre of good ground, well ſtocked with this graſs, near Kingſton or Spaniſh town, is computed to bring in above a hundred and twenty pounds a year; and when once planted holds many years: but when the main ſtalk or root grows hard or woody, the younger ſhoots do not puſh ſo luxuriantly, and they are then obliged to plant anew; this however is eaſy, being done gradually, for the pieces are generally ſupplied as they clean them, by throwing up every ſtubbed or failing root they find, planting a few joints in the place

56. Guinea-grass is increased in the same manner, but does not require near so much moisture, and is reckoned a more hearty fodder. It is not so much cultivated as it ought to be. The lands about the towns are too subject to drought to produce it in any perfection; and in the other parts of the country they are too indolent to be at the trouble of planting it; not considering how much time and labour is lost in seeking for other fodder, which is not so good, and cannot so easily be obtained; nor do they consider the losses they sustain in stock, for the want of abundance of good wholesome food[1].

Class. 13. 1. Polyandria Monogynia.
Nat. order of *Rhoeadeæ. Papaveraceæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* two-leaved, ovate, emarginate: *leaflets* subovate, concave, obtuse, caducous.
COR. *Petals* four, roundish, flat, spreading, large, narrower at the base; alternately less.
STAM. *Filaments* numerous, capillary, much shorter than the corolla. *Authers* oblong, compressed, erect, obtuse.
PIST. *Germ* roundish, large. *Style* none. *Stigma* peltate, flat, radiate.
PER. *Capsule* crowned with the large stigma, one-celled, half-many-celled, opening by many holes at the top under the crown.
SEEDS numerous, very small. *Receptacles*, longitudinal plaits; the same number with the rays of the stigma, fastened to the wall of the pericarp.
OBS. *The pericarp is either globular or oblong, and differs in the rays of the stigma. The primary division of the species is to be taken from the smoothness and roughness of the pericarp.*

ESSENTIAL CHARACTER.

Cal. two-leaved. *Cor.* four-petalled. *Capsule* one-celled, opening by holes under the permanent stigma.

DESCRIPTIONS, *&c.*

1. The leaves of the *Bastard Poppy* are much smaller than those of the common Corn-Poppy, and are cut into much finer segments. The stalks are slender, little more than a foot high, and not so branching as *P. Rhoeas*. The flowers are not so large, and of a deep purple colour, seldom lasting more than a whole day. The oblong prickly capsules are filled with small black seeds.

[Leaves doubly pinnatifid, with linear and nearly equal divisions; terminating pinna trifid; upper side nearly smooth: nerves of the under side covered with strong hairs pointing upwards. Branches and pedunicles channelled, covered with hairs of the same sort. Calyx oval, with a few hairs, larger and broader than the *P. Argemone* [b]. Petals small, dark dirty scarlet. Filaments deep purple. Anthers pleasant blue [c]. Capsule with six furrows like a melon [d], or from six to ten, with as many rays to the stigma [e].

Native of some of the Southern parts of Europe, and of England, among corn: as near Norwich, and Wells in Norfolk; the Parks Oxford, and Eynsham, Oxfordshire; about Durham. It flowers in june and july.]

2. Leaves finer cut and smaller than those of the common sort, but not so fine as those of the preceding. Stalks not so high as either, seldom having many branches. Flowers not half so large, of a copper colour, and falling away in a few hours. They appear in may, and are succeeded by long slender channelled capsules, filled with small black shrivelled seeds.

[Leaves pinnate; pinnas opposite, decurrent, lanceolate, deeply pinnatifid; the terminating one trifid; the upper side nearly smooth; the nerves of the under side and petioles rough with diverging hairs. Stem and peduncles covered with hairs pointing upwards. Calyx hairy. Petals wedge-shaped, narrow [f]: or, according to Withering, obovate, scarlet, with a black spot towards the base, white before the calyx opens. Germ inversely conical. From five to eight rays to the stigma. The capsule has the same number of cells as the stigma has rays; it is ribbed, and the strong hairs or bristles on it are white and point upwards.

Stalks a foot or more in height, bending upwards; where it grows luxuriantly it puts forth several, but among corn it is commonly found with a single upright one. Leaves next the root numerous, on long petioles. The hairs on the calyx issue from small papillæ or prominent points. Petals finely notched at top. Filaments about twenty, purple. Pollen blueish. Germ the length of the filaments, thickest at top, somewhat angular; the hairs gray and pressed to it. Rays of the stigma from three to five, villose, blueish. Capsule for the most part naked below, of a purplish colour. Seeds blackish.

The divisions of the leaves are finer in this than in any of the other Poppies; the petals in general grow more upright, and instead of having the edges falling over each other, are usually a little distant; the filaments are uncommonly dilated at top not at the base, as Haller asserts; and the anthers stand on a very slender pedicel placed on the top of each filament.

Like most of the other Poppies, it usually grows in corn fields, and is not unfrequent about London. It flowers at the beginning of june, and is often overlooked from the extreme fugacity of its petals [g]. It is a native not only of most parts of Europe, but of the Levant. This and the preceding are annual plants.]

3. Leaves smooth, with the segments finely cut. Stalks about a foot high, sustaining one small yellow or copper-coloured flower, succeeded by a roundish prickly head.

[The Poppy of the Alps is a little perennial plant hairy all over; the stems are naked and simple, with a bundle of leaves at the base; the leaves are winged; the first and the last leaflets are simple, the middle one larger, often trifid; the corolla is yellow, reddish or whitish; the capsule is oblong, with the upper part five-cornered. It grows in high rocky places, exposed to the wind, and bare of grass [h].

Scopoli remarks, that the variety with a yellow flower is not so hairy; that the segments of the leaves are more long and slender, with the last only trifid; and the stamens from sixty to seventy: he ascribes to this the synonym from Dillenius which belongs to *nudicaule*. The variety with a white flower is, according to him, a larger and more hairy plant, with paler leaves, all the pinnas trifid and wider, with the claws of the petals greenish. Segtier's figure seems to belong to this; the yellow variety not having sessile gashed pinnas.

Linneus, in his *mantissa* says, that the calyx is hirsute; the petals white with a yellow base; and the capsule ovate with five stigmas.

According to Haller, the leaves are commonly hirsute, but in the Swiss plant smooth; the stem a long span in height; the calyx brown and very hirsute; the corolla small, flaccid, white with a yellow claw, the yellowness frequently diffusing itself over the whole petal. Under the flower, as in *P. Argemone*, is a pencil of hairs of a dark-brown colour. The whole plant, when fresh, has a strong smell of musk. Neither Haller nor Scopoli distinguish this from the next species.

Native of Switzerland, Austria, Carniola, Dauphiné, Piedmont, Silesia.

4. Roots slender, whitish, fibrous (annual or biennial). Root-leaves many, hispid, the lowest broader and shorter, less deeply divided into fewer and broader segments; the leaves next above are divided into many narrower and longer segments, glaucous green especially underneath. From among these leaves arises a single naked stalk, sometimes two, a long span or a foot in height, somewhat glaucous, hispid, sustaining one flower of a middling size, like that of *P. cambricum*, but of a paler yellow colour, the two inner petals a little smaller, the two outer somewhat larger. Filaments very many, yellowish, with broadish compressed striated anthers. Germ roundish, greenish,

[a] Woodw. Mſs. [b] Relhan. [c] Linn. [d] Robson. [e] Woodw. Mſs. [f] Curtis. [g] Villars.

with

with eight rays on the top. Capsule roundish-oblong. Seeds black when ripe. The flower has a fine sweet smell like the Jonquil, especially morning and evening. The seeds were sent from the eastern confines of the Russian empire, from the province of Argunsky in Siberia, in latitude 51° by Heidenreich, and were sent to the Eltham garden, with those of several other plants by J. H. de Sprekelsen[1]. It was therefore cultivated there in 1730. It varies with white and with yellow flowers; which appear from june to august[2].

Linnæus says, the peduncles and calyxes are hairy; and that the leaves are less divided; but that it is so nearly allied to the preceding, as to give room to suppose it to be the produce of culture.

5. Stem from one to two feet high, upright, round, branched, purplish at bottom, with spreading hairs bulbose at the base. Leaves sessile, forming a kind of sheath at bottom, hairy on both sides; the segments or leaflets unequally toothed or serrate, each tooth rolled back at the edge, callous at top, and terminated by a small spine. Peduncles long, round, upright, one-flowered, the hairs on it spreading horizontally. The two calyx-leaves are hispid, membranaceous at the edge. Petals bright full scarlet. Stigma convex, with ten or twelve rays, of a purple colour. Capsule, not globular, as Linnæus terms it, but shaped like an egg with the broad end cut off, (or, as Dr. Withering has it, urn-shaped, and nearly as broad as it is long) marked with as many raised lines as there are rays to the stigma; which is flat and scalloped on the edge. Seeds dark purple[3].

Native of every part of Europe, the Levant, Japan, &c. and much the most common with us of any of the species, in corn-fields; also on dry banks and on walls, in such situations varying in its foliage, but still retaining the urn-shaped capsule, and spreading hairs. It flowers from june to august[4]. Being so common a weed it has many provincial names in English, besides its more classical ones of Corn Poppy, and Red or Scarlet Poppy; such as Corn-Rose, Cop-Rose or Cup-Rose in Yorkshire, Canker or Canker-Rose or Redweed in the Eastern counties, Head-wark, &c.

The petals give out a fine colour when infused, and a syrup prepared from this infusion is kept in the shops, more for the sake of the colour, than of any active principle the flowers possess. This species partakes in a small degree of the same properties with *P. somniferum*[5]. The capsules, as in that, contain a milky juice, of a narcotic quality, but the quantity is very inconsiderable. An extract from them has been successfully employed as a sedative; and some foreign practitioners even prefer this extract to opium[6].

There is a variety with an oval black shining spot at the base of each petal, from which many beautiful garden varieties originate[7].] These have double flowers, white, red bordered with white and variegated.

[6. This species resembles the preceding so much, as often to be mistaken for it. But the capsules of this are long and slender; the hairs on the peduncle are finer, and pressed upwards close to it; on the young peduncles they assume a shining silvery-white appearance, which is very beautiful; on the other parts of the plant the hairs spread out; the stalks and leaves are much paler; the flowers much smaller, and less intensely red[8].

Dr. Withering also remarks, that a strict attention to the proportionate length and breadth of the capsule, and to the hairs of the peduncle being laid close or spreading, will always distinguish this species from *P. Rhœas*. According to him, the segments of the leaves are entire, the edges and midribs hairy; rays of the stigma from six to ten.

Dr. Withering mentions a variety, with the whole plant very hairy, figured in *Flora danica*, 902.—It seems, he says, to be an intermediate plant between *P. Rhœas* and *dubium*, if it be not a distinct species. The bristles on the peduncles are laid close, as in the latter, but the segments of the leaves are very much snipt at the edges. The calyx is studded with large transparent globules, and a taper bristle springs out of each. The capsule is nearly twice as long as it is broad, so that it is longer than in *P. Rhœas*, but shorter than in *P. dubium*. It is found about Shankline Chine, and in pastures in various parts of the Isle of Wight.

P. dubium is native of several parts of Europe. According to Mr. Lightfoot, it is the most common species in North Britain; and in Battersea field, says Mr. Curtis, where the soil is light, it is nearly as common as the *Rhœas*; nor is it unfrequent on walls. About Cambridge, Oxford, Stockwell in Surry, Bocking in Essex, &c.—This, as well as the preceding, is annual.]

7. The Common White Poppy has the stalks large, smooth, five or six feet high, branching. Leaves large, grayish, embracing at the base, irregularly jagged on their sides. Flowers terminating, whilst inclosed in the calyx hanging down, but before the corolla expands becoming erect. The calyx is composed of two large oval grayish leaves, that separate and soon drop off. The corolla is composed of four large, roundish, white petals, of short duration; and succeeded by large roundish heads as big as Oranges, flatted at top and bottom, and having an indented crown or stigma. The seeds are white. There are several varieties, differing in the colour and multiplicity of their petals, which are preserved in gardens for ornament; but that with single flowers only is cultivated for use.

β. The Common Black Poppy has stalks about three feet high, smooth and dividing into several branches. Leaves large, smooth, deeply cut or jagged on their edges, and embracing. Petals purple with dark bottoms, succeeded by oval smooth capsules filled with black seeds, which are sold under the name of Maw-seed. There are many varieties of this with large double flowers, variegated of several colours; red and white, purple and white, and some finely spotted like Carnations: there are few plants whose flowers are so handsome; but having an offensive scent, and being of short duration, they are not much regarded. They are both annual and flower in june.

[Linnæus remarks the smoothness of all the parts in this species; the stem, leaves, calyx and capsule. The rays of the stigma are ten, or thereabouts, and the half-internal divisions as many.

The officinal Poppy is a native of the Southern parts of Europe, but probably came originally from Asia, where it is cultivated in great quantities.

The general history of Opium and its virtues has been so judiciously detailed by Dr. Woodville, in his Medical Botany, that we shall here insert the most material part of that author's information.

Opium, called also Opium Thebaicum, from being anciently prepared chiefly at Thebes, has been a celebrated medicine from the remotest times. It differs from Meconium, which was made by the ancients of the expressed juice or decoction of the Poppies. It is imported into Europe in flat cakes, covered with leaves, to prevent their sticking together: it has a reddish brown colour, and a strong peculiar smell: its taste, at first, is nauseous and bitter, but soon becomes acrid, and produces a slight warmth in the mouth: a watery tincture of it forms an ink, with a chalybeate solution. According to the experiments of Alston, it appears to consist of about five parts in twelve of gummy matter, four of resinous matter, and three of earthy, or other indissoluble impurities.

The use of this celebrated medicine, though not known to Hippocrates, can be clearly traced back to Diagoras, who was nearly his contemporary, and its importance has ever since been gradually advanced. Its extensive practical utility however has not long been well understood; and in this country perhaps may be dated from the time of Sydenham. Opium is the chief narcotic now employed: it acts directly upon the nervous power; diminishing the sensibility, irritability, and mobility of the system; suspending, according

[1] Dillenius. [2] Hort. kew. [3] Curtis. [4] Idem. [5] Withering. [6] Woodville. [7] Woodw. Mis. [8] Curtis.

according to the idea of a late ingenious author, the motion of the nervous fluid to and from the brain, and thereby inducing ſleep, one of its principal effects. From this ſedative power of Opium, by which it allays pain, inordinate action, and reſtleſſneſs, it naturally follows, that it may be employed with great advantage in a variety of diſeaſes. Indeed there is ſcarcely any diſorder in which, under ſome circumſtances, its uſe is not found proper; and though in many caſes it fails to procure ſleep, yet if taken in a full doſe, it occaſions a pleaſant tranquillity of mind, and a drowſineſs, approaching to ſleep, which always refreſhes the patient. But, beſides the ſedative power, it is alſo known to act, more or leſs, as a ſtimulant, exciting the motion of the blood; and this increaſed action has been aſcribed ingeniouſly and, as we think, rationally, to that general law of the animal œconomy, by which any noxious influence is reſiſted by a conſequent re-action of the ſyſtem. By a certain conjoined effort of this ſedative and ſtimulant effect, Opium has been thought to produce intoxication, a quality for which it is much uſed in the Eaſtern countries.

In moſt of the continued fevers of this climate, though originating from contagion, or from whatever cauſe, there is generally at the beginning, more or leſs of inflammatory diathesis; and this, while it continues, would forbid the uſe of Opium, which might prove dangerous. Its uſe is alſo forbidden in the more advanced ſtate of this fever, whenever topical inflammation of the brain is aſcertained, which ſometimes exiſts, and produces delirium, though other ſymptoms of the nervous and putrid kind prevail. But when irritation of the brain is not of the inflammatory kind, and debility has made much progreſs, or where delirium is accompanied with ſpaſmodic affections, Opium is a ſovereign remedy, and may be employed in large doſes every eight hours, unleſs a remiſſion of the ſymptoms and ſleep take place. In intermittent fevers Opium, in combination with other medicines, was much uſed by the ancients; but ſince the introduction of Peruvian bark it is ſeldom truſted to for the cure of theſe diſorders: it has however been ſtrongly recommended as an effectual means of ſtopping the recurrence of the febrile paroxyſms; and has been given before the fit, in the cold ſtage, in the hot ſtage, and during the interval, with the beſt effects, producing immediate relief, and in a ſhort time curing the patient, without leaving thoſe abdominal obſtructions which have been aſcribed to the bark; but in theſe fevers, the beſt practice ſeems to be that of uniting Opium with the bark, which enables the ſtomach to bear the latter in larger doſes, and adds conſiderably to its efficacy.

When Opium is ſo managed as to produce ſweat, it will tend to remove an inflammatory ſtate of the ſyſtem, and may prove generally uſeful: a notable inſtance of this we obſerve in the cure of acute rheumatiſm by means of Dover's powder. In the ſmall-pox, Opium, ſince the time of Sydenham, has been very generally and ſucceſsfully preſcribed, eſpecially after the fifth day of the diſeaſe; but during the firſt ſtage of the eruptive fever, we are told that it always does harm; an opinion (ſays Dr. Woodville) which our experience at the ſmall-pox hoſpital warrants us to contradict. In hæmorrhages the uſe of Opium is inferred from its known effects in reſtraining all excretions except that of ſweat; but unleſs the hæmorrhages be of the paſſive kind, or unattended by inflammation, it may produce conſiderable miſchief. In dyſentery, Opium may be occaſionally employed to moderate the violence of the ſymptoms. In diarrhœa, when the acrimony has been carried off by a continuance of the diſeaſe, it is a certain and efficacious remedy. In cholic it is employed with laxatives, and no doubt often prevents inflammation by removing the ſpaſm.

Opium has lately been commended in venereal caſes; and inſtances have been adduced in which it has ſucceeded where mercury had failed: but few practitioners, we apprehend, will truſt to Opium alone in theſe complaints. Opium is ſucceſsfully uſed in tetanus, and in other ſpaſmodic and convulſive caſes.

Reſpecting the external uſe of Opium authors are not agreed; ſome contending, that when applied to the ſkin it allays pain and ſpaſm, and procures ſleep, while others affirm, that when thus applied it has no effect whatſoever. Applied to the naked nerves of animals, it produces torpor, and loſs of power in all the muſcles with which the nerves communicate. Opium taken in an immoderate doſe, proves a narcotic poiſon, producing vertigo, tremors, convulſions, deliriums, ſtupor, ſtertor, and finally, fatal apoplexy.

The officinal preparations of this drug are Opium purificatum, pilula ex opio, pulvis opiatus, tinctura opii, and tinctura opii camphorata. It alſo enters into the pulvis ſudorificus, ballamum anodynum, electuarium japonicum, pulvis e creta compoſita, &c.

The requiſite doſe of Opium varies in different perſons, as well as in different ſtates of the ſame perſons. A quarter of a grain in one adult, will produce effects which ten times the quantity will not do in another; and a doſe that might prove fatal in cholera or cholic, would not be perceptible in many caſes of mania or tetanus. The loweſt *fatal doſe*, to thoſe unaccuſtomed to it, ſeems to be about four grains; but a dangerous doſe is ſo apt to occaſion vomiting, that it has ſeldom time to occaſion death. When given in too ſmall a doſe, it often produces diſturbed ſleep, and other unpleaſant conſequences; and on the other hand, a ſmall doſe will ſometimes produce ſound ſleep, and alleviation of ſymptoms, when a larger one would not have ſucceeded. Its general operation is ſuppoſed to laſt about eight hours. It is well known, that by continued habit, Opium may be taken in large quantities; and we are told by Garcias ab Horto, an inſtance in which it was increaſed to ten drams a day. About twenty drops of the tinctura thebaica, or Laudanum, are conſidered as nearly equivalent to a grain of Opium. Thoſe who are addicted to the uſe of Opium in the Eaſtern regions will ſometimes take incredible quantities.

The White Poppy is commonly conſidered as the officinal plant, but any of the varieties may be employed indiſcriminately, ſince no difference is diſcovered in their ſenſible qualities or effects.

The heads or capſules are alſo powerfully narcotic or anodyne; boiled in water they impart their narcotic juice. The liquor ſtrongly preſſed out, ſuffered to ſettle, clarified with whites of eggs, and evaporated to a due conſiſtence, yields an extract, poſſeſſing the virtues of Opium, but requiring to be given in double the doſe. It is ſaid not to occaſion a nauſea and giddineſs, which are the uſual effects of Opium. It is convenient to prepare the ſyrup from this extract, by diſſolving one dram in two pounds and a half of ſimple ſyrup. The *ſyrupus Papaveris albi*, as directed by both colleges, is an uſeful anodyne, and often ſucceeds in procuring ſleep, where Opium fails. It is more eſpecially adapted to children. White Poppy heads are alſo uſed externally in fomentations, either alone, or more frequently added to the *decoctum pro fomento*.

The ſeeds poſſeſs not any narcotic power: they conſiſt of a ſimple farinaceous matter, united with a bland oil, and in ſome countries are eaten as food. As a medicine they have been given in the form of emulſion, in catarrhs, ſtranguries, &c.

Opium is imported into Europe from Perſia, Arabia, and other warm regions of Aſia. Six hundred thouſand pounds of it are ſaid to be annually exported from the Ganges.

It appears that the Poppy may be cultivated for the purpoſe of obtaining Opium to great advantage in Britain. Profeſſor Alſton, of Edinburgh, ſaid long ſince, that the milky juice, drawn by inciſion from Poppy heads, and thickened either in the ſun or ſhade, even in this country, has alſo the characters of good Opium; its colour, conſiſtence, taſte, ſmell, faculties, phænomena are all the ſame; only, if carefully collected, it is more pure and free from feculencies.

Similar remarks have been made by others; to which, ſays Dr. Woodville, we may add our own; for during that ſummer (probably 1792) we at different times made inciſions in the green capſules of the White Poppy, and collected the juice, which ſoon

acquired a due conſiſtence, and was found, both by its ſenſible qualities and effects, to be very pure Opium. May I be permitted to add, that near fifty years ago, I frequently amuſed myſelf with ſlaſhing the green Poppy heads, and collecting a moſt pure and well digeſted Opium from them.

But the merit of firſt cultivating the Poppy for Opium is due to Mr. John Bull, of Williton, who in the year 1796 was rewarded by the Society of Arts, Manufactures and Commerce, for procuring Opium in an unſophiſticated ſtate from Britiſh Poppies, and communicating his mode of preparing it, to the Society, for the uſe of the public.

When the leaves die away and drop off, the capſules or heads being then in a green ſtate, is the proper time for extracting the Opium, by making four or five ſmall longitudinal inciſions with a ſharp-pointed knife, about an inch long, on one ſide only of the head, taking care not to cut to the ſeeds: immediately on the inciſion being made, a milky fluid will iſſue out, which being of a glutinous nature, will adhere to the bottom of the inciſion; but ſome are ſo luxuriant, that it will drop from the head. The next day, if the weather ſhould be fine, the Opium will be of a grayiſh ſubſtance, and ſome almoſt turning black; it is then to be ſcraped off, with the edge of a knife, into pans or pots; and in a day or two it will be of a proper conſiſtence to make into a maſs, and to be potted.

As ſoon as the Opium is all taken away from one ſide, make inciſions on the oppoſite ſide, and proceed in the ſame manner. The reaſon of not making the inciſions all round at once is, that the Opium cannot ſo conveniently be taken away; but every perſon, upon trial, will be the beſt judge. Children may with eaſe be ſoon taught to make the inciſions, and take off the Opium; ſo that the expenſe will be trifling.

An inſtrument might be made, of a concave form, with four or five pointed lancets, about the twelfth or fourteenth part of an inch, to make the inciſions at once.

Mr. Ball calculates, that ſuppoſing one Poppy to grow in one ſquare foot of earth, and to produce only one grain of Opium, more than 50lb. will be collected from one ſtatute acre. But ſince one Poppy produces from three or four to ten heads, in each of which from ſix to ten inciſions may be made, each inciſion ſometimes producing two or three grains; what muſt be the produce? and what the profit at the preſent price of Opium, 22s. the pound *?

I am ſenſible that great abatements muſt be made in practice from ſuch theoretical calculations as theſe; and that in our moiſt climate many ſeaſons will occur, and many days in almoſt every ſummer, unfavourable to the collection of the Opium. It is however, with all its diſadvantages, a very important object to cultivate the Poppy for this purpoſe in Britain; conſidering the great price of foreign Opium, the increaſing call for it in medicine, the adulteration of what is imported by rice flour and other articles, and the employment that it will find in the collection for women and children.

Mr. Ball adds, that in 1795 from a bed of ſelf-ſown Poppies 576 feet ſquare, he collected four ounces of Opium, though the plants were very thick: and from a few plants that ſtood detached he took from fifteen to thirty-four grains: this ground had been well manured with rotten dung. He remarks that the ſemi-double flowers, and thoſe of a dark colour produced the moſt Opium: that the heads ſhould be about the ſize of a walnut before the inciſions are made; and that the foreign dried Poppy heads are full three times as big as ours †. Mr. Miller remarks alſo that they are of a different ſhape; but the ſize is only owing to climate, and the ſhape indicates no more than a variety.

Mr. Ball collected from one ſemi-double Poppy a quantity which he ſuppoſes to be more than thirty grains; but this plant had twenty-eight heads on it. He prefers the double and ſemi-double flowering plants to thoſe which have ſingle flowers. But I have obſerved that the ſingle Poppy, cultivated by our phyſic-gardeners here for the ſeed and the heads, have generally larger heads than the double Poppies cultivated in gardens.
